The bill to establish a State Reformatory or School of Industry at Ione, Amador county, appropriates $160,000 for its establishment and maintenance. It is to be managed by a board of directors. Boys under 18 years of age may be committed by a Superior Judge upon complaint of any authorized person who shows to the satisfaction of the Judge that it will be to the best interest of the boy to have him sent to the school. The board also has the power to discharge or parole a boy. Any fugitive from the institution may be arrested and returned on the written order of the superintendent.

The bill provides for the payment of the expenses of each inmate, and requires the superintendent to furnish a per capita statement of expense. The building must not exceed $40,000 in cost, the barns, sheds and work-shops, $10,000, and the tools and machinery, $10,000. Habits of industry and thrift are to be encouraged, and every comfort of the inmates is to be assured, and their moral and physical advancement taken into consideration. This is the first State institution established on the mineral belt of the State.

The Senate has passed the bill appropriating $50,000 to purchase a site for the Home for Feeble-Minded Children within Santa Clara county, and $120,000 for the erection of buildings.

It has also passed a bill appropriating $30,000 to the State Board of Forestry.

Hamill's Senate Water Meter bill was passed, but owing to a flaw in the title, it was ordered re-engrossed. The bill provides that water companies must put in meters at their own expense. The consumer may require the company to test the meter every three months at the company's expense. No meter can be used at all until tested by the official gas and water inspector.

HARTSFELD FURNACE FAILURE.—A Montana mining paper having published notices of the merits of the Hartsfeld portable smelter, at Milo, Idaho, Mr. Horace F. Brown writes that it is a failure. He says: "No man there will now claim any merit for the furnace. No man with the least practical knowledge of the matter ever believed a word of the specious claims of the Hartsfeld outfit, but because it was supposed to be cheap and within the reach of men of moderate means who had a small mine, several have been sold with the same result, a total loss to the purchaser. The only other furnace of the type in the West was erected at Cooke City, and proved a more disastrous failure than this one, because a more persistent effort was made to use it and much greater expenses incurred."

INDUSTRIAL EXHIBITION. — The Mechanics' Institute will open its 24th Industrial Exhibition in this city on Aug. 27th, and close it October 5th. Medals of gold, silver and bronze, with an engraved diploma, will be awarded to such articles as may be found to merit special distinction, and competent jurors will be appointed to examine and report on the same, unless the owner shall, at the time of their reception, give notice they are for exhibition only. The Department of Machinery will be enlarged and specially prepared for machinery in motion, for which ample steam and power will be furnished, including water.

ASBESTOS.—J. D. Hoff and F. T. Botsford purchased from Murray & Co. of San Diego what is known as the asbestos mines on the desert. These mines are situated in San Diego county, between Dos Palmas and the Cuyamaca ranch, on the line of the Cuyamaca railroad. For about three months Mr. Hoff has been negotiating for these mines. The asbestos being very long fibered, some of it two and three feet long, is of very fine quality. The asbestos has to be carried on mules and wagons for 36 miles.

ACADEMY OF SCIENCES.—At the last meeting of the Academy a paper was read by Dr. Geo. Heuston on "Crinoids or Sea-Lilies." Some specimens of fossil ivory were exhibited by J. H. Burnham, the Folsom banker. The specimens were found by M. P. D. Eckhardt in a placer mine situated three miles from Folsom, near the old camp of Prairie City, and were found in a bed of gray gravel, 22 feet below the surface. The pieces, five in number, form an almost perfect elephant's tusk.

COST OF OPERATING A MINE.—The cost of operating the Con. Cal. and Va. mine for the month of January was $150,724.14, and included $43,080 for salaries and wages, $23,232.26 for mine supplies, $72,324 for reduction of ores, $510.32 for transportation and hauling, $10,332 for royalties to the Sutro Tunnel Co., $550 for water rent, $367.60 for compressed air, and $1639.47 for assaying.

STANDARD MINE.—At the annual meeting of the Standard Mining Co. of Bodie, the following officers were elected for the ensuing year: Aug. Pettibone, Pres. and Gen. Manager; Jos. Tate of New York, Vice-Pres.; and T. C. Grant, Act. Pres.; W. H. Oscanyon of New York, P. N. Lilienthal, A. P. Brayton, and John Mason, directors. J. W. Pew was re-elected Sec'y. The secretary's report showed a cash balance of $20,723.97.

THE Coloma people will provide refreshments for the legislators on March 2d, on the occasion of the unveiling of the Marshall monument.

Nevada City Mines.

(*Continued from page 127.*)

and salt. Sulphuric acid is bought in tanks, which effects a saving in freight and breakage as compared with carboys. The ore is exposed to the action of chlorine during 48 hours. The gold is precipitated from the leach by solution of sulphate of iron.

Dimensions of roasting furnace, inside, 70 by 10 feet; capacity of roasting furnace, 3 tons in 24 hours; consumption of wood for roasting one ton, three-fourths of a cord; number of gassing tubs, 4; number of gold-precipitating tubs, 3; number of silver-leaching tubs, 3; number of silver-precipitating tubs, 3; dimensions of gassing tubs, inside diameter, 80 inches; dimensions of gassing tubs, inside depth, 30 inches; capacity of gassing tubs, 3 tons; dimensions of precipitating tub, inside diameter, 72 inches; dimensions of precipitating tub, inside depth, 36 inches; time of charge in chlorine, 48 hours; consumption of chemicals to one ton of ore: manganese 6 pounds; salt in furnace, 40 pounds; salt in generator, 6 pounds; sulphuric acid of 66 degrees B., 20 pounds.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco.

VALLEY LUMBER CO., Feb. 9. Capital stock, $300,000. Directors—T. K. Prescott, C. S. Pierce, F. P. Hooper, C. A. Hooper, C. F. A. Talbot, A. P. Talbot and W. H. Talbot.

UNITED STATES BREWERY CO., Feb. 12. Capital stock, $1,000,000. Directors—Frederick Kronenberg, Philip Rohrbacher, Markus Schwab, Ferdinand B. Koenig and Robert H. Countryman.

PALACE BATHING CO., Feb. 13. Object to furnish salt-water baths. Capital stock, $100,000. Directors—Alonzo Trueworthy, Albert E. Ridley, Francis F. Du Rose, John S. Marshall and Charles J. King.

GOLDBERG, BOWEN & CO., Feb. 13. Object, to do a general grocery business. Capital stock, $200,000. Directors—Jacob Goldberg, Charles R. Bowen, Daniel L. McShane, Henry A. Bowen, Hugo D. Keil and George W. Whitney.

MORTON-BROWN CUTTER AND CUTTER-BAR CO., Feb. 15. Object, manufacturing and selling cutters and cutter-bars for mowers, reapers and headers, and all other kinds of agricultural implements. Capital stock, $100,000. Directors—W. F. Goad, John W. Coleman, Lloyd Tevis and C. B. Stone.

OBED CHART AND LAND ASS'N. Object, to acquire and dispose of lands in the city and county of San Francisco. Capital stock, $500,000. Directors—George Mearns, George Hearst, J. de Forest, J. B. Lewis, G. W. McNear and W. H. Rouse.

FOX PLATFORM AND COUPLING CO., Feb. 19. Object, to manufacture and deal in car-platform couplings, etc. Capital stock, $500,000. Directors—Frank A. Fox, Lyman C. Parke, Benjamin T. Lacy, William B. Wilshire and Squire Mooney.

N. C. CARNALL CO., Feb. 19. Object, mercantile purposes Capital stock, $100,000. Directors—N. C. Carnall, Wm. M. Fitzhugh, Geo. W. Hopkins, M. W. Bell and Alexander Gordon. Capital stock, $100,000, in 1000 shares.

Mining Share Market.

The market in mining shares has been rather more active this week than for some time past. As the lack of ore-crushing power has been cited as the cause of the long era of depression in Comstock share values and trading, now that that cause is removed, the long-promised revival in both prices and business volume should come.

In speaking of the long-continued depression on prices of shares, the Virginia *Enterprise* says: How long this state of affairs will continue is beyond our ken, but it will doubtless keep on until some very important ore strike is made in some one or more of our leading groups of mines. The long-drawn dry spell of weather has had something to do with this, of course, but not all. An immense stream of water has been fooling around a Pelton wheel at the Nevada mill, and distressing electric motors, which could have been used to crush 250 tons of ore daily at the California mill if the condition of the mine warranted it—and the management was willing. Stock operators have put these facts together with their private information, and they have been wary to tackle a market supported by mines whose ores were worked at a decided loss. The generous snowstorm, which has prevailed here for the past 24 hours, cannot fail to give a better tone to the market, of course. But that would seem to be dependent upon the opening up of valuable ore bodies in our mines, in the fact that a power is created to reduce the ore, for we are not much better off with ore and no water than we are with water and no ore.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Lexington, Feb. 15, $23,216; Cons. Cal. and Virginia, 16, $56,684; Savage, 10, $24,848; Challenge (for January), $15,781; Overman, 16, $7476; Hale and Norcross, 19, $16,800; Alice, 13, $25,480; Moulton, 12, $12,834; Hanauer, 13, $1850; Justice, 20, $2925; Hanauer, 14, $2250; Standard, 20, $5727; Confidence, 20, $16,407; Hanauer, 15, $2450; Bluebird, 14, $16,244.

SILVER DISCOUNT.—The Alice mine of Montana produced last year $487,242 on silver reckoned at $1.29 per ounce, the old standard value. The discount, however, was $134 971. The loss on silver was greater than during any other period, President Walker estimating the average selling price at 93.87 per fine ounce.

THE fire in the Calumet and Hecla mine is once more on the increase, and there is serious danger of it spreading into No. 2 shaft.

Iron Railroad Ties Wanted.

Some time ago an official of the Erie railroad is reported to have said:

"Railroad ties need renewing every three years. In building a new road the estimate is 2700 ties for each mile. It is safe to say that it will require 300 ties per mile per year to keep a road in repair. From 12,000,000 to 15,000,000 new ties are required by the railroads of the United States every year. In building the great Western railroads the contractors in many cases purchase outright the timber along the routes or as near to it as possible. In that case they pay from $20 to $25 an acre for the land. If they contract simply for the ties they pay from 10 to 12 cents apiece for them to the owner of the land for all the ties taken out. The average price paid to the tie contractor is 35 cents apiece, although we have paid as much as 50 cents for the best oak ties. Hewn ties are better, in our estimation, than sawed ones, and we use no others. Some companies think as well of sawed ties as of the hewn ones. The theory of our people is that the hewn tie lasts much longer than the others. It is only within the past few years that hemlock has been used to any extent in making railroad ties, but we find that it can be used to advantage in many instances on sidings and sections of track where the traffic does not require constant repairs. This road pays to the tie contractors along the line about $400,000 a year. Stone, iron, paper, and even glass have been used in making railroad ties, with the hope that they could be practically adopted as a matter of economy in that department of the expenses of railroads, but none of them have yet been utilized with satisfactory results. The annual clearing off of a quarter of a million acres of timber to supply railroads with ties alone is something that should direct the attention of those who are interested in the important question of protection to forests to the finding of some practical substitute for wooden ties. Fame and fortune await the inventor who will discover such a substitute."

Geo. W. Thompson, formerly a rancher and partner with one of the proprietors of this journal in a 220-acre ranch near Oakland, who is now at Sag Harbor, N. Y., has made what he believes to be a practical and valuable improvement in metal railroad ties. The drawings and descriptions of the same can be seen at this office. It will soon be illustrated in the MINING AND SCIENTIFIC PRESS, in order that its merits may become widely known.

Mr. Wanamaker's Testimony.

There is too much impartial testimony as to the value of advertising to allow of the impeachment of the value of a newspaper's advice on the subject.

The words of John Wanamaker of Philadelphia ought to have weight with men engaged in mercantile business. He says: "I spend $5000 a week in advertising, and I pay a skillful man—a former newspaper editor, and a good one—$1000 a month to do it for me. I make money by it. Advertising is the leverage with which this store has been raised up. I do not see how any large and successful retail business can be done without liberal advertising. I advertise in every issue, except Sunday, of every daily paper in Philadelphia. Continuous advertising, like continuous work, is the most effective."

Now, what has been the experience of this man, to make him so appreciative of the value of printer's ink? Mr. Wanamaker began life without a cent to his name. His father was a bricklayer and he himself went into a clothing store as a clerk when he was 14 years old. From that humble beginning he worked himself up by dint of energy and enterprise until now he is proprietor of what is probably the largest retail store in the United States.—*Waterbury Republican.*

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

MINE TAXES IN COLORADO.—The case of the Iron Silver M. Co. of Leadville against the Treasurer of Lake county, Colorado, to restrain him from collecting taxes on their property, upon the ground that the mine-tax law of 1887 was unconstitutional, has been decided by Judge Goddard, whose decision fully sustains the constitutionality of the law.

THE eight Chinese hydraulickers in the Yuba county jail owe an aggregate of 2119 days' service, having served less than half their term. Friends are negotiating for their release on the payment of money, but the Yuba authorities have decided that to accept less than a dollar for a day would be to commute the sentence and hence illegal.

COPPER.—A correspondent writes us from Hollister, San Benito county, that copper has been found lately near Tres Pinos, and there is quite an excitement about the claims, which promise well. Several parties from San Francisco and San Jose have been investigating the find.

STEPHEN THOMAS has been appointed foreman of the Sierra Buttes quartz mine. W. M. James, superintendent, has gone to Shasta county, temporarily, to look after mining property there, recently purchased by the Sierra Buttes Co.

THE Pennsylvania Mining Company's mill at Jackson Creek, Nev., was burned last week. It was valued at $15,000.

JAMES LEFFEL'S

Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, Feb. 21, 1889.

General trade is steadily improving. About all the traveling salesman are on the road, and, with few exceptions, their reports are of a favorable character. They tend to show that in the agricultural districts the cooler weather has, for the present, allayed fears regarding the crops, and with timely, well-distributed rains, the grain yield of the State will be the largest for years. The outlook for wool is good, as are the prospects for a large crop of fruit, and also for other farm products. Immigration continues to set this way, creating a good demand for farming land and settling up the many sparsely populated localities in several of the counties. In the local money market, it is stated that the demand continues good for accommodations on country realty, which, to some extent, is met by the savings banks in this city. On city realty there is only a fair inquiry. From merchants the demand for accommodations is only fair. From the speculative interests the call was lighter from operators in cereal options, owing to the general bear influences on the market. The same can be said of mining stocks. The general public, it is said, have very little faith in the stability of the latter, believing that the present move is only made to make a few short fills. While this may be so, every indication warrants the assertion that stocks appear to be bought up by strong parties, whether for a deal or for other purposes, is, as yet, a mystery. From the mining districts, our advices are quite favorable. Large deposits of snow in the mountain ranges are reported to have been made within the past fortnight, with more snowstorms looked for within the next 30 days. The deposit of snow insures a longer supply of water, and therefore a reasonable assurance that mining will be extended well into the summer months. This, perhaps, is more particularly the case with the mines on the Comstock lode, Virginia City, where the fear of a scarcity of water has exerted a decidedly unfavorable influence, notwithstanding the news from the work going on in the leading mines indicates important developments at an early day. Much of this work the MINING AND SCIENTIFIC PRESS gave in its last two issues, but which is only now finding its way into the columns of our daily cotemporaries. In Crown Point they expect to soon commence stoping out ore from the rich deposits left from the "Bonanza days," as soon as a mill for crushing is secured, for which negotiations are now said to be pending. With better air connection in Crown Point, Belcher and Seg. Belcher, which is about completed, active exploration of the 1300 level will be commenced. In Challenge, Yellow Jacket, Alpha, Con. Imperial, Gould and Curry, Best and Belcher, and the North End mines very important work is under way, although air connection in the near future must be made in the Union from the drift known as the 146 foot Ophir drift. In the Middle mines the work is progressing well, with an improvement reported in two. In Con. Virginia a further improvement is reported on the 1650-foot level. From the Tuscarora, Bodie and Quijotoa districts our advices continue favorable.

Later advices than given above, received from a reliable source, state that there was quite an improvement in Alpha the past week, while in Mexican good milling ore was run into on the 1465-foot drift. From the same source we are informed that a crosscut will be started next week on the 1465-foot level, near the north line of Mexican, and one in Union near the south line.

Con. Virginia, Confidence and Hale & Norcross, it is claimed by those who should know, will pay dividends in next month.

Exchanges on European money centers and also on New York are very strong, but the impression prevails that after next week the rates will slacken off, for the idle money generally sent out of the State to avoid assessment will be recalled, when there will be more sellers than buyers of exchanges.

The London *Money* of January 19th says that the value of the silver exported to the East last year from that city was £7,807,400, and the average price for the year was 42⅞d., the lowest average yet recorded, the average for 1887 being 44⅝d.; for 1886, 45⅜d.; and for 1885, 48⅝d. The amount of bills and telegraphic transfers drawn in England on Indian Governments last year was £13,964,700, against £15,394,000 in 1887.

SILVER—The market has exhibited a firm, strong tone, with a slight advance secured. It now looks as if New York is exerting a stronger influence than ever before on the market. The fluctuations in silver will no doubt cause the metal to attract more attention for speculative purposes. The feeling that exchanges will shade off has a direct bearing on silver in our market, causing the latter to lose the premium above the New York parity. The supply of silver with us is still light, but there is every assurance that the output of the mines, now that more water is had, will be largely increased within the near future. The price, at the close, in this city, is given at 93¼c bid, although an advance on this was paid for spot parcels for shipment by to-morrow's steamer for China.

QUICKSILVER—The market was inactive at a shading in prices. As there has been quite a deposit of snow the past fortnight in the mountain ranges on this coast, an improved call for quicksilver is looked for.

LEAD—The inquiry for Alaska and Columbia river, noted last week, is continued, although not so marked. Prices are without essential change.

TIN—The market for plate shows a steady tone for both spot and early arrival. Pig is weaker. Alaska and Oregon are now drawing their spring supplies.

IRON—The market for spot is slow, with holders living in the hopes of an improved call at an early day. The stock in the warehouses is large, but to arrive, it is small.

COPPER—The market appears to be shaping into better position, but no decided advance in prices is looked for, owing to the large mine-owners and also the syndicate apparently working to keep values down at as low a paying basis as possible, so as to keep outside mines from being developed to any great extent.

COAL—Spot coals are lower, but for just shipped or to be promptly shipped, holders are firm. There is a feeling that a further reduction in prices is not at all likely, but this opinion obtained before the last decline. There is no denying but there is a strong selling pressure or competition on the part of some of the coast mine-owners.

Eastern Metal Markets.

By Telegraph.

NEW YORK, Feb. 21, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42⅝	93	$16 65	$3 65	$21 35
Friday	42 9-16	93	16 60	3 65	21 20
Saturday	42 9-16	93⅛	16 60	3 65	21 25
Monday	42⅝	93¼	16 60	3 66¼	21 50
Tuesday	42 11-16	93¼	16 50	3 65	20 90
Wednesday	42 11-16	93¼	16 50	3 67½	21 05

Quicksilver is quiet at 60@61c. Borax—Steady, with small sales. Refined and powdered California, 6¾@9⅜c; concentrated, 7¾@8¼c. The iron industry is not satisfactory. Steel rails are extremely dull, with no positive improvement. January's foreign export was better than for that of the same month for the previous two years. Copper is dull and quotations nominal. Tin is firmer at the decline. Lead has a steadier tone at the close.

By Mail.

The following is the latest from the "New York Metal Exchange Market Report":

Prices generally ruling for metals not regularly dealt in on Call at the N. Y. Exchange, covering extremes of buyers' and sellers' views. All prompt delivery. Australian Tin, $21.80@22.00; Billiton Tin, $22.25@——; Banca Tin, $22.25@23.50; Baltimore Copper, ——@——; Orford Copper, $16.00@16.25; P. S. C. Copper, ——@——; Foreign Lead, $4.75@5.00; Foreign Spelter, $5.95@6.00; Antimony, Hallett's, $11.25@11.37½; Cookson's, $13 @13.25.

THE cleanup of the Young America Company, Sierra City, for January, was $27,200, and a dividend for the past month of $10,000 has been declared.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class Engine and Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

For New Subscribers—Something New and Rare.

PACIFIC COAST RELIEF CHART.

PHOTO-FACSIMILE.

With subscription paid one year in advance for this paper, and 10 cents to pay postage and mailing tube, we will send a fine Photoplate Relief Chart of the Pacific Coast, embracing California, Nevada, Oregon, Washington Territory, and part of Montana, Idaho and Utah. Photographed from a topographical relief model in plaster (5 feet 3 inches by 5 feet 6 inches in size), made recently by Isaac Winston and Prof. Geo. Davidson (the latter Chief of the U. S. Coast Survey on this Coast for the past 20 years).

While it does not take the place of an ordinary map, it illustrates, comparatively, the elevations and depressions of the principal mountains, valleys, rivers, lakes, ocean and bay-shores of the Pacific States and Territories, and makes a permanently useful, handsome and desirable picture for either library, office or home.

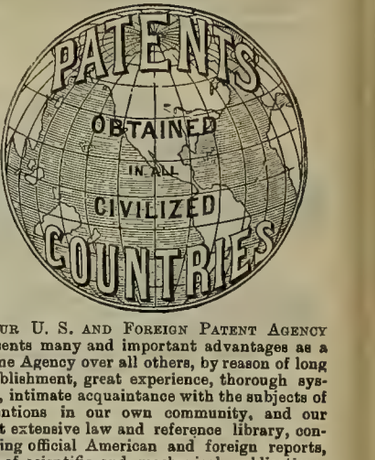
The charts are 19x24 inches, well suited for framing, if desired. It is as handsome, and even more durable, than an ordinary photograph. Seldom is so choice an article offered as a newspaper premium. Sent to old subscribers on the same terms on paying one year in advance of current date. Subscribe and secure this permanently valuable chart.

Address Publishers of this paper, No. 220 Market St., S. F

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER

Dewey & Co.'s Scientific Press Patent Agency.



OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Books on Working Ores.

BY GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty PRICE, $3, cash, postage free. Sold by DEWEY & CO., Publishers, 252 Market St., San Francisco, Cal.

BY C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by DEWEY & CO., S. F.

SHARES IN A GOLD MINE.

A limited number of shares of Buffalo Con. G. M. Co.—a developed and working mine in Sierra County, California—will be sold, in order to procure additional appliances in connection with the water supply. The mine has a mill and is producing good rock. The shares are non-assessable and held among a few owners, and none of them have been put on the stock market.

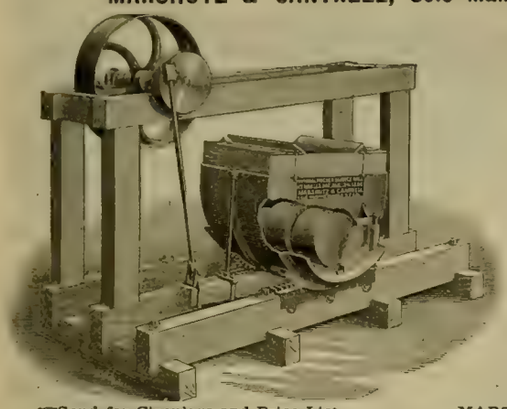
NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

☞Send for Circulars and Price List. MARSHUTZ & CANTRELL.

PACIFIC COAST AGENTS,

PARKE, LACY & CO., San Francisco.

Books on Assayin .

BY C. H. AARON.

PART I.—Gold and Silver Ores.—Price $1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, $1, postpaid. Sold by DEWEY & Co., Publishers, No. 220 Market street, San Francisco

PARTS II AND III.

Lead, Copper, Tin, Mercury, etc. Price $1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion, Assaying Bullion; Humid Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parkes' Process; Amalgamation; New Process; Preparation of Potassium Zanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Salt; Appendix to Part I; Notes on Crucible Assays; Weighing by Oscillations; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume which is bound strongly in cloth. Price postpaid, $1.75 Sold by DEWEY & Co. Publishers, No. 220 Market St., S.F.

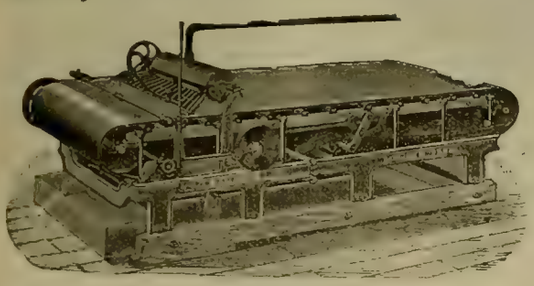
THE
FRUE ORE CONCENTRATOR
OR VANNING MACHINE.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,
Room 15, No. 132 Market Street, - - - - - - - SAN FRANCISCO, CAL.

$1,000 CHALLENGE ACCEPTED,

PRICE, FIVE HUNDRED AND FIFTY DOLLARS
($550.00).



The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

54-INCH BY 16 FEET STEEL BOILERS IN 2 SHEETS.

Cal State Library 31 '89

STEAM USERS, ATTENTION!

The engraving represents our standard 54 in. x 16 ft. Boiler. These boilers are made of homogeneous STEEL, and the shell, as shown, being in TWO PIECES, the advantage of this will be readily appreciated by steam users.

There are NO SEAMS in the fire to leak, nor loose rivets to contend with, caused by the continual expansion and contraction of the plate on account of the unequal distribution of the heat under the boiler, the bottom presenting a smooth, even surface which can be easily cleaned. We place a manhole at the back end above the tubes, and one in the front end under the tubes.

The FRONT MANHOLE gives free access to the sheet over the fire, THE VITAL PART OF EVERY BOILER. This point is often overlooked by purchasers, and boilers are supplied with a small hand hole, and the remaining space filled with tubes which allows absolutely no access for cleaning, and in a short time tubes and sediment are one solid mass, and instead of gain in efficiency by a few feet of tube surface, the result is a positive loss.

SPECIFICATION OF BOILER AND FIXTURES:

1 Boiler, 54 inches diameter by 16 feet, with 46 3½-inch tubes; Shell, 5-16; Heads, 7-16.
1 Steam Drum, 36 inches diameter by 72 inches long.
1 Breeching.
1 Smokestack, 30 inches by 60 feet, Nos. 12 and 14 Iron.
300 feet galvanized strand for Guys.
1 C. I. Front, complete.
1 Foundation Plate for front.
1 Set Grate Bars for coal or wood.
1 Back Bar Bearer.
1 Ash Cleaning Door and Frame.
1 Back Arch Plate.
1 Set Binder Braces and Bolts for Brickwork.
1 Stand for back end of Boiler.
1 Steam Gauge and Syphon.
1 Glass Water Gauge, complete, with column and 3 Gauge Cocks.
1 Safety Valve.
1 Stop Valve.
1 Feed Valve.
1 Blow-off Valve.
1 Check Valve.

These Boilers are tested to 150 pounds hydrostatic pressure and are intended for a working pressure of 100 pounds. Total weight of Boiler and fixtures, 17,000 pounds.

☞ BOILERS ON HAND READY FOR SHIPMENT. ☞ SEND FOR CIRCULARS.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

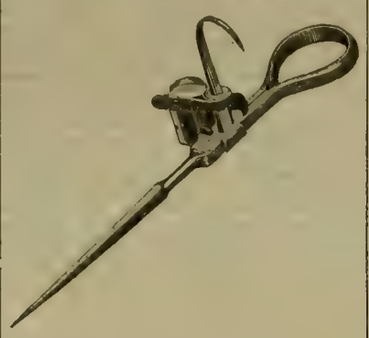
A Miner's Candlestick.

Gabriel Werntz of Placerville, El Dorado county, has invented a candlestick for miners' use which has several improved features. The handle portion, as shown in the engraving, is bent around into the form of a ring, the two ends being extended parallel with each other. The inner adjacent faces of the two sides are channeled in V form, so that as they lie together the channels form a square or diamond shape in cross section, into which the correspondingly shaped inner end or shank of the spear will slide and fit. A hole is made through one of the sides, and a corresponding notch is formed in the shank of the spear, so that a transverse pin or key passing through will hold the spear firmly in place between the two sides. This key is shown as extended upward so as to form the hook, by which the device may be hung up whenever it is more convenient to secure it in this manner than by striking the spear into a wooden beam.

The candle is held in a tubular socket. This socket is made of spring steel bent into cylindrical form and having a projecting thumb-piece upon one side, by which it may be sprung open sufficiently to admit a candle. This socket may either be secured permanently on the side of one of the extensions, or may be provided with lugs, which extend down through one of the sides, passing through the V-shaped channel in that side, and having notches cut in them so that when the spear shank is inserted into its place between the two sides it will engage these notches, and thus lock the candle-holder lugs firmly in place.

The hook, having been inserted into the slot before described, will lock the spear in place, and the whole will be firmly held together. The length of the candle-socket is such that if the candle becomes broken it may be so placed in the socket that the broken place will be held within the length of the socket, and thus keep it in place until the candle is burned down to this point, and so prevent waste.

In order to prevent danger from accident, an automatic extinguisher is employed, which consists of a disk secured to the end of the arm, which is attached to or forms an extension of the spring, having a central hub, which fits over the square shank of the hook. The disk is drawn back when the candle is introduced into the socket, and its edge then rests against the side of the candle, the pressure of the spring being sufficient to hold it in this position with considerable force. When the candle has burned down to the disk, the latter will be forced across the candle, thus cutting it off and extinguishing it, so as to prevent accident. By this construction of the jointed and detachable spear the inventor is enabled to make a candlestick of greater length, so that there is not so much danger of the candle igniting dry wood which may be near it, and when it is desired to carry it away, it is easily separated by



Werntz's Miners' Candlestick.

removing the key, the extinguishing disk, and reversing the spear, placing the hook and disk upon the handle and holder.

When everything is conveniently packed up it can be put into the pocket and carried away. The inventor is desirous of disposing of the patent rights for the Pacific Coast.

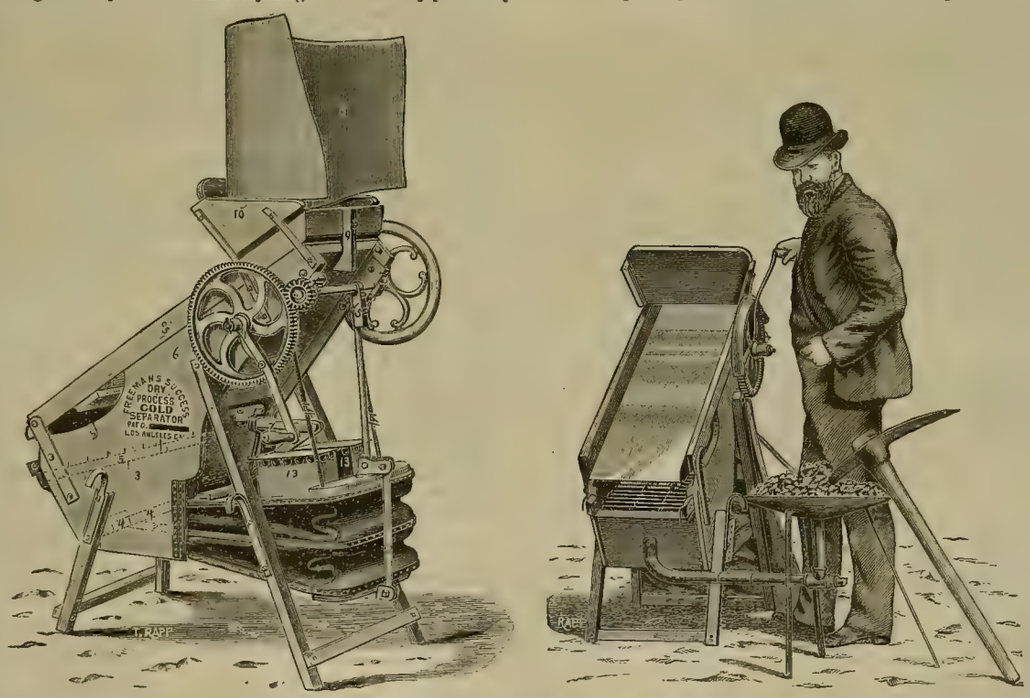
MECHANICS' INSTITUTE.—The election of the Mechanics' Institute on Tuesday was quite an exciting one, but the following trustees, all on the regular ticket, were elected by a large majority: Irwin C. Stump, Chas. F. Bassett, S. J. Hendy, John Mallon, David Farquharson, Geo. E. Dow, Carlton Newman. These will serve for two years.

BILLS have been introduced in Congress providing for the admission into the Union of Idaho, Wyoming and New Mexico.

Freeman's Dry-Gold Separator.

We have received a large number of letters from different parts of the country asking for a description of the Freeman Success dry process for obtaining gold from placers, gravel, sand, etc., without the use of water. This machine has been successfully operated at various places, and an item relating to its work at Osceola, Nev., brought out the inquiries referred to. The machine is intended to be operated by hand, but other power may be applied. It is so constructed as to withstand the excessive heat in hot climates without checking, and is easily taken to pieces so as to be packed on burros. The 50 ton machine, complete, weighs 120 pounds. This machine will require from five to six men to supply dirt to operate it to full capacity, but it can be worked to good advantage with two men. To produce a light machine of great capacity that will save the gold has been the object of the inventor, and this has been accomplished by producing a peculiar action of the air upon the debris, gravel or dirt.

The accompanying engravings illustrate the device. In operating the machine the debris is thrown into the receiving hopper (11) and falls upon the screen, which is jarred by the crank shaft striking the bumper (9) at every revolution. The large stones pass off and the finer material falls into the hopper (6), is fed on to the apron (5) by the valve (7), and is carried along and off the apron by the action of air. The top and lower bellows are connected with the iron strap (12). The dividing board (2) separates the bellows (1–1). The pitman strap (15) connects the bellows with the crank shaft. By reference to the cut it can be seen that in revolving the crank shaft, both bellows are forced downward at the same time, the top bellows ejecting the air through the valve (4) into the air-chest (3), while the lower bellows is receiving air. On the upward motion the bottom bellows ejects the air, while the top bellows receives it. By this means, at every revolution of the crank, two currents of air are forced into the air-chest, one at once following the other. On the top, and completely covering the air-chest, is placed the apron (5) containing the riffles for catching the gold. The feed valve (7) is operated by an adjustable lever held firmly to a ratchet bar fastened to the bellows. By this means the feed is increased or decreased as desired, and is also caused by the raising and falling motion of the bellows to open and close, thereby preserving an even flow of the debris to the apron. As the bellows are put in motion, rapidly succeeding currents of air are forced into the air-chest, and are there retained until a sufficient pressure is obtained to force the air out through the apron, which is of close mesh, being constructed with a layer of wire cloth of 120-mesh underneath, which is a layer of light canvas. This assures an even flow of air throughout the entire surface of the apron.



FREEMAN'S DRY PROCESS GOLD SEPARATOR.

Three distinct results are obtained by the action or pressure of air caused by the two bellows and the close mesh of the apron: First—The current of air passing up through the apron slightly raises the gravel and sand therefrom, and, as it passes through the debris, the particles of sand and gravel are crowded apart, making avenues for the gold to settle to the apron.

Second—At the first puff of air the debris is carried outward over the apron about one inch, when the crank shaft makes its dead center, it allows a momentary cessation of air and the debris is caused to pause but only momentarily, as the succeeding current o air at once picks it up and carries it along. There is imparted to the gravel and sand by this quick action in stopping and starting, a jerk which results in causing the gravel to roll, thereby creating a complete separating and parting of the debris, and allowing the gold to settle easily to the apron on which it is retained by the riffles.

Third: At the first puff of air, the debris is raised slightly from the apron by the force of air escaping. At the momentary cessation of air caused by the crank making its dead center, the debris pauses and starts to descend; but before reaching the apron, the succeeding current of air causes it to slightly ascend, thereby imparting an up-and-down movement to the debris while it is passing over the apron. It also prevents any rubbing or friction of the debris upon the wire cloth, for the reason that when the bellows are in operation the current of air buoys up the debris and prevents it from falling upon the apron.

The action obtained in this separator is pro-

(*Concluded on page 149*).

CORRESPONDENCE.

We admit unindorsed, opinions of correspondents.—EDS.

The Sprague Electric Railroad.

EDITORS PRESS:—I have read your editorial article on electric railroads in California, in the last number of your paper, with much interest. I agree with you in the main, but I think you do not give quite enough credit to successes in the East, as the article may be interpreted as giving your support to those who have doubts as to the success of any electric railway system.

I do not see how any one can doubt the success of the Sprague system, when it is so highly indorsed. Let me give some of the best indorsements. Here we have a hard-fisted old Quaker in Wilmington, Del., writing an unsolicited letter to the Sprague Company, in which, among words of praise, the following very plain statement is made:

"The system has been in operation here for three months, and from a practical experience during that time, we can pronounce it a complete success." While in Los Angeles I showed the copy of that letter to a gentleman who knows that old Quaker, and of whom he made the remark like this: "He squeezes a dollar for every cent there is in it, and when I see his name signed to such a paper, I consider it of value."

Then we have a letter from the Union Passenger people of Richmond, Va., in which are the following statements in regard to the Sprague equipment there: "The road, which you have equipped under most trying conditions, has been one of the most difficult, if not *the* most difficult, which could be met with in street-railway work. We must confess that we have sometimes shared the doubts that others have been so free to express as to the possibility of the successful completion of this work, and hence it is with the greatest pleasure that we acknowledge the successful fulfillment of all the terms and conditions of the contract and compliment you upon having achieved so signal a success." Mark in the above that all the conditions and terms of the contract were fulfilled.

Mr. Whitney, president of the West-End system of Boston, a system of over 200 miles of street railway, stopped in his preparations for putting cables on one of the branches of the system, visited Richmond and gave the road there a most thorough investigation, returned to Boston and declared to the selectmen of Brookline that "it is a success in all respects," procured a franchise, and then contracted with the Sprague Company for the equipment.

Then may be cited the very rapid introduction in other places, due to the inspection of the system by other companies, and orders for additional equipments by companies already using the system, and for the equipment of roads in towns where our system has been in operation for some months. The latest indorsement of importance is from the Pennsylvania R. R. Co. It is recognized that this corporation is the best equipped road in America, and it is not likely that they would contract for anything that is not thoroughly reliable. Within the last few weeks they have entered into a contract with the Sprague Company for the equipment of their system of street roads in Atlantic City, N. J. The contract was signed after an investigation of the principal electric roads in this country, continuing over five months, by a committee of mechanical and electrical experts of high standing; and it was given on account of the demonstrated reliability and economy of running, together with excellence of mechanical and electrical details. I consider that this is as good an indorsement as could be given to any railway system.

When one considers that on Feb. 1, 1888, the Sprague Company had not completed a single road, and that to-day it has about 15 in operation and contracts for enough more to make over 30 when all are completed, it is very apparent that there must be something behind the reports of the great successes of the system.

I have yet to learn of an unsuccessful road equipped by the Sprague Company, and I am willing to leave the decision as to the successes to the officials of the roads which have been equipped, or to the city officials or the prominent citizens in any of the towns where Sprague motors are used.

The persons to whom you refer in your editorial must never have seen a Sprague equipment; perhaps their investigations were made before the completion of the first one. I will admit that the people of this coast have been unsuccessful in their electric railway ventures, and they have my sympathy in their financial misfortune, due to poor investments. To them I would say that the Sprague Company's experimenting—for of course it was necessary to experiment—was done at their own expense; but having excellent principles as the basis, it proved to be an excellent investment.

On the strength of the testimony which I have brought to bear, and the desire to have interested parties give our roads personal and careful investigation, can you not recognize as such a successful railway system, without doing an injustice to yourself?

JOS. L. JAYNE,
Agent Sprague Electric Railway & Motor Co.

How Powder is Made.

The California Powder Works.

[Written for the PRESS.]

Having had the pleasure of recently visiting the California Powder Works, and believing that a brief mention of the works, together with the process of making powder, may be interesting to some of the readers of the PRESS, I submit a few items as obtained through the courtesy of Col. B. Peyton, superintendent of the works, and his son William C. Peyton.

The works are located in the valley of the San Lorenzo, about three miles north from Santa Cruz. This site was chosen because of the abundant supply of water accessible and the splendid facilities for shipping; and their isolation from other public and private enterprises is quite a desideratum.

The canyon, or narrow vale in which they are located is thickly set with eucalyptus and the smaller growth of the historic redwood. Here the rollicking San Lorenzo is never silent, and in almost every direction the artful little flumes can be seen coursing their tiny way to the busy wheels. There are about

Five Miles of These Flumes,

Forming a pretty network, some under foot and some over head.

From beginning to end there are quite a number of processes in making powder, the machinery required for each being isolated from that of any other department. In company with Mr. Peyton Jr. and a lady friend, we visited the various departments and found none wanting in interest.

There are some 70 to 80 men employed at the works. A public school is maintained in the vicinity; the narrow-gauge branch of the S. P. runs hard-by, hence the employes are wanting in none of the ordinary privileges and comforts of other manufacturing communities—except, as we were informed, they must forego the pleasures of the large bonfires which usually illumine other less explosive parts during the political campaigns.

On the cliff surmounting the east bank of the San Lorenzo, at an altitude of nearly 400 feet, is Col. Peyton's elegant residence. The cliff is almost perpendicular, which enables Mr. Peyton to overlook the entire works at a glance from his residence.

Col. Peyton came to California 43 years ago, having been a resident of Santa Cruz 23 years, during which time he has established a manufacturing enterprise the product of which finds a market in

South America, the Sandwich Islands,

Throughout the United States and Alaska. He also ships to Kamtschatka. The product is about 10,000 kegs per month. The kegs, cans and flasks are all made at the works, the manufacture of which is within itself of no small interest.

During a period of 20 years there have been only five explosions, in all of which but five lives were lost.

The essential feature of manufacture is the mixing of three ingredients—charcoal, sulphur, and either nitrate of potash for sporting powder, or nitrate of soda for blasting powder. Three varieties of woods are used for making the charcoal—madrona, willow and alder. The latter makes the best charcoal, while madrona is used only for the low-grade powders. The desiderata for a good charcoal wood are three, viz.: Freedom from resinous matter, the absence of hard concentric rings of growth, and a minimum of deliquescent salts in the ash. The wood, before being charred,

Must be Thoroughly Dry.

The charring is done in cast-iron retorts, provided with exit tubes for the volatile constituents of the wood, and heated in furnaces specially prepared for them. This operation takes one day, and is conducted at a temperature of from 500° to 600° F.

Belgium sulphur is used altogether for making gunpowder, and is refined when it reaches the works.

The nitrate of potash, or saltpeter, comes from India, and when received is quite impure, containing, besides earthy matter, jute from the bags, etc., a large quantity of chlorides and sulphates. These chlorides are very objectionable, as they greedily absorb moisture from the air and would carry that undesirable feature into any powder in which the impure saltpeter might be incorporated. The saltpeter, together with some water, is placed in large copper tanks which contain a perforated worm connected with a steam pipe. The steam is turned on, and soon all the niter passes into solution, while the pieces of jute, straw, etc., come to the top and are carefully skimmed off. A solution of glue is then added and the steam again turned on. This glue goes to the bottom and forms an envelope around each particle of sand, dirt or grit and buoys them to the top of the solution, whence they are easily removed. The niter is now free from all deleterious substances except the foreign chlorides. The removal of these is the next operation, and is dependent upon the well-known facts that salt is equally soluble in both hot and cold water, while saltpeter is much more soluble in the former than in the latter. If, then, a boiling concentrated solution of these two substances be allowed to cool, the niter alone will separate out, while all the salt, together with a part of the niter, will remain dissolved. The hot liquor from the copper tanks is run off into large wooden crystallizing vats, and while cooling is constantly agitated to prevent the formation of large crystals which would occlude some of the saliferous mother liquor. The saltpeter as fast as it separates from solution is placed in hoppers, when it is allowed to drain, after which it is dried on a large iron plate heated from beneath. It is then pulverized between burr-stones and is then fit to be manufactured into the best gunpowder. It does not contain more than 1-6000 part of foreign salts.

The nitrate of soda, used solely for blasting powder, is of itself a deliquescent salt, hence it is only necessary to remove from it the grit and sand, the presence of which would be

Highly Dangerous

During the process of manufacture. It is obtained in bulk from Chili, where it is partially refined to remove the iodide of soda, an important source of the iodine of commerce. To purify the nitrate it is melted down in two large iron kettles, whence it runs into a third smaller kettle. The grit here settles to the bottom, while the pure nitrate is removed from the top by a wheel through which cold water circulates. A knife placed close to the surface of this wheel scrapes off the film of niter, which is then ground to an impalpable powder. It is thus not only freed from all grit but is also thoroughly dried.

The sulphur and charcoal, 10 parts of the former to 15 of the latter, are placed in iron barrels filled with gun-metal balls. These barrels revolve on horizontal axes and the balls crush the charcoal and sulphur to the proper degree of fineness. This mixture is then carried to the incorporating mills, where it is thoroughly mixed with 75 parts of niter. These mills consist essentially of two iron wheels, weighing seven tons apiece, which revolve upon a cast-iron bed. By the combined rolling and grinding action of these wheels, a very thorough incorporation is effected. This is at once the most important and the most dangerous part of the manufacture. It is the most important, for upon the thoroughness of the incorporation depends in great part the strength of the powder; it is the most dangerous because if the wheels should ever touch the bed

An Explosion Would Immediately Ensue.

This danger is in great part obviated by the presence of wooden plows, which, revolving with the wheels constantly, throw the powder in front of them. The time of incorporation varies greatly. For blasting powder it is but two hours, while for some of the higher-grade sporting powders it is as much as 12 hours. As a general rule, the longer the time, the more thorough the mixing and the better the powder. From these mills the powder goes to the press, where it is subjected to a pressure of 2000 pounds to the square inch. The powder is pressed in layers between copper plates, and when it comes from this mill it is very hard and in the form of plates two feet square and half an inch thick.

In the corning mill this "press cake" is passed, first between gun-metal rolls containing projecting teeth whereby it is broken up into lumps, and then between smooth zinc rolls by which it is crushed to the requisite degree of fineness.

The glaze contains large wooden cylinders, running upon a hollow shaft containing hot water. The powder from the corning mill is glazed by the attrition of one grain upon the other, and is at the same time dried. To the blasting powder, toward the end of the operation, is added a small amount of black lead, which gives it a very bright finish. This is not used for sporting powders, as it retard the rapidity of combustion.

The different sized grains are separated by passing through a series of superimposed sieves, those of larger sized mesh being on top, those of smaller mesh being on the bottom.

Nothing now remains to be done save to pack the powder and place it on the market.

W. C. PERSHBAKER and Magalia Gold Mining Co. intervenors ask that judgment in the case of Wm. Gregory and Wm. Singer vs. Pershbaker and M. G. M. Co., rendered in the Superior Court of Butte county, be set aside and a new trial granted, and that Gregory and Singer be enjoined from taking any gold from the mine in controversy.

THE Solano *Times* says: There are $100,000 worth of tools on the way from the East for the Mare Island iron-plating shop construction department, which will commence to arrive in about two weeks.

THE annual report of the Indian Department of Canada says there are encouraging indications that the Indian element will eventually become amalgamated with the general population of the country.

CATFISH are so numerous in Washoe Lake that the Nevada people want the Legislature to import a carload or two of alligator gars to thin out the catfish.

THE meeting of the Northern California publishers and editors at Sacramento is to be held March 18th.

THERE are four smelting companies in Butte, M. T., with about 65 caloine and matte furnaces altogether.

Electric Street Railroads.

At the first meeting of the California Electrical Society the following paper was read by John C. Henry of Kansas City, and more recently of San Diego, who is the inventor of the Henry system for electric roads:

In complying with the very complimentary request to prepare a paper on the subject of electric railways, to be read at one of the first meetings of the recently organized "California Electrical Society," I hesitate with these thoughts uppermost in my mind: What is to be the future of this society? Will its papers be preserved and scanned over by the coming electric historians? Can I, a humble worker in this fascinating field, pen anything worth preserving? Will the predictions made be verified? In anticipation of its prospective future, I regret that it must be a forced article, prepared without reference or proper consideration, by a visiting stranger in your city.

To give a preliminary history of the state of the art, and its gradual development, the chestnuts must fall.

The first historic reference to electricity is, I believe, to be found in the Bible: "Canst thou send the lightnings that they may go and say unto thee, Here we are?" The interrogation remained unanswered for many centuries, until "Franklin caught and tamed the horse which was harnessed by Prof. Morse." The discovery of the first process for making electricity is credited to Alessandro Volta during the year 1770. It is said to have come about in this way: He was toying with two pieces of coin in his mouth, one of copper, the other of a spurious metal. He placed one above and the other below the tongue. When the edges of the two metals came in contact he noticed a peculiar taste and its absence when they were separated. This led to the construction of the

First Electric Battery,

Known as Volta's Pile. It consisted of a large number of laminations of sheets of copper, zinc and moistened cloth. Here the stored-up energy in the metal zinc was released. This metal's dissolution gave birth to heat, light and force. This is a beautiful exemplification of Nature's law, that nothing is lost. I am told your society has members who are fresh and ambitious in the study of electricity, and this paper should be within their understanding. It will be greatly to their advantage to remember this law. They may release the stored-up energy in coal and produce heat. With the heat releases the gases, from which the water is composed. In turn drive steam engines.

By their force generate electricity, which appears again in the form of magnetism, light and heat, and yet nothing is lost. It is simply a conversion of energy from one form to another. It is not in man's power to make or destroy one atom. One Christmas morning, in 1821, Michael Faraday, whose name will be remembered when kings are forgotten, first discovered electro-magnetism. In 1826 Prof. Joseph Henry, late of the Smithsonian Institution, starting with the principles discovered by Faraday, succeeded in producing a magnet capable of sustaining several thousand pounds. Following up his brilliant discoveries, in 1831 he constructed a telegraph system. Later on he invented the relay which made long-distance telegraphy possible. During the same year he wrote Prof. Silliman as follows: "I have lately succeeded i producing motion in a little machine by

Magnetic Attraction and Repulsion."

This is supposed to be the first electric motor ever constructed. Although fully realizing the value of his inventions, Henry saw the production of power by the consumption of zinc was a very expensive process. In 1832 Sturgeon of London produced a rotary electro-magnetic engine. In 1835 Thomas Davenport, a Vermont blacksmith, exhibited in Springfield, Mass., a model of the first electric railway. In 1850, Dr. Page, aided by Congress, operated a large electric motor on a road near Washington. These experiments demonstrated Henry's predictions that the cost of the zinc precluded the possibility of commercial advantage. The failure here arose from the fact that

Zinc Cost a Great Deal

More than coal and contained much less energy. For a time this seemed to be an insurmountable obstacle to electric railway engineers. In 1831 Prof. Faraday, while searching for reciprocal action from a magnet, discovered that by passing a closed wire near the poles the movement was resisted by the magnet and the lost energy appeared in the coil of wire in the form of electricity. This is a pure case of induction. The law governing it was formulated by and is known as Lenz Law. It is the foundation of all dynamo-electric generators and motors. One loop of wire was succeeded by a multiplicity of loops, which to-day are revolved at a high rate of speed before the face of powerful magnets in all modern dynamos. Remembering Lenz's law, the current induced is of such a nature and in such a direction that it tends to resist the motion which produces it. The revolving of the loops of wire (technically called the armature) resists the power of the initial force, let it be a steam engine, water-wheel, or any other. The consequence is this spent energy, which must appear again in some form, is led from the machine and is made to do useful work, such as heating the wires, burning lamps or transmitting power. So perfect are some of the modern dynamos constructed that 93 per cent

of the energy put into them is made to appear again in the form of electricity. The balance is wasted in heating the copper wires of the machine and the mechanical causes. Following

This Sketch of Development,

It leads us to a very large and weak machine as permanent magnets alone had been used. During the year 1870 it occurred to a number of experimenters about the same time to use a portion of the circuit to energize the field magnets of its own machine with powerful temporary electric magnets.

This grand step forward appears to have been conceived of simultaneously by scientists in several different countries. This invention secured the commercial use of dynamos, and then the different electric-light companies began their work. To retrace our steps a little, we find, by considering Lenz's law, it is easy to formulate a converse one. The dynamo resists the power of the steam engine and a current of electricity is generated. A second dynamo placed in the circuit tries to stop the current from flowing, and its armature is forced backward.

Pacinotti's Invention.

I must not pass the history of the development of the art without referring to Pacinotti's invention, which was fully described in an Italian journal in 1864. It consisted of a dynamo machine, and its reversibility was plainly pointed out. In other words, by applying power to its armature, a current was generated. By giving its current from an external source, it developed power. Strange to say, a working model of this lay buried and forgotten in the University at Pisa for over 20 years, until after it had been reinvented. In 1879, Siemens Bros. exhibited at the Berlin Exhibition a small electric locomotive supplied by current from a dynamo machine. Previous to this, in all experiments, the energy came from batteries carried on the cars. On this road the iron rails carried the current to the moving motor from a stationary source. About the same time the writer, whose long experience with currents on telegraph lines impressed him with the importance of good insulation, conceived the idea of

Placing the Conductors Over the Track.

Work was immediately commenced on the designs of an electric railway system, and preparations made for protecting the invention by patents. The details consisted of stationary dynamos, electric conductors leading therefrom supported over the route of the cars by guy wires to posts at the sides of the street, and a traveling contact held firmly to the wires by spring pressure, which was connected to the car by flexible conductors. So perfectly were the details worked out at this time, that their principles are in use on 98 per cent of the roads in operation to-day. Owing to your author's forced residence on the plains, a thoroughly practicable demonstration was not made until 1884, when a street-car was fitted out and operated on one of the Kansas City horse-car lines. In the mean time demonstrations were being made with surface and conduit conductors by different inventors. In the spring of 1885, the Kansas City Experimental road was inspected by Chas. J. Van Depoele, one of Chicago's most prominent electricians. He regarded it as a complete solution of the electric-railway problem, and immediately commenced the construction of roads. His work has since extended to nearly every State in the Union. To-day there are some 50 roads in operation and hundreds more projected and undergoing construction. Having completed a cursory view of the historical part, we will turn to the practical side of the question.

What Advantages have Electric Roads

Over others? This can be best understood by an analysis of those systems in general use.

The early history of railroading brings us back to the tram roads in the English mines, where animals were used to haul wagons loaded with coal on iron tracks. Next, the animals were displaced and the cars moved by cables driven by stationary engines, and finally the cables were generally succeeded by locomotives. This change commenced some 75 years ago. To-day the modern locomotive has developed into a strong and reliable machine built upon the principles thoroughly demonstrated by George Stephenson in 1814. It contains nothing new in principle. Owing to peculiar construction, it is far from being economical. The best results ever obtained with locomotives is the consumption of eight pounds of coal to the horse-power developed per hour. The Risdon and Union Iron Works in your city to-day are building stationary and marine engines that will develop a mechanical horse-power for every two pounds of coal consumed. Electric roads derive their power

From Economical Stationary Engines

Or the forces of nature, such as waterfalls, etc. Here we have an indicated saving of about 75 per cent. For many centuries the ingenuity of man has been directed to the flying problem. The prime causes of failure arise from the fact that birds weigh much less in proportion to their strength than man does. This analogy is very suggestive when comparing the electric with the steam motors, particularly so when elevations are to be ascended, as a very large percentage of the power of the locomotive is lost in lifting its own weight. As a matter of fact some of the modern locomotives which are capable of developing 300 horse-power weigh 60 tons. An electric motor could be made to develop this same power and not weigh ten tons. Steam railway engineers will tell you it requires this weight to get sufficient adhesion. This is a fallacious idea when connected with electric motors. On our San Diego road we have frequently taken two cars, containing about 150 passengers, up a grade of 450 feet to the mile with a motor weighing but 2000 pounds, and depend upon the adhesion of but one pair of wheels. With this load we frequently stopped and started on this grade. I am strongly of the opinion, and it is the

Result of Close Observation

And study of the action of locomotives, that there is not one of any weight in this State to-day that can stop and start again on the same grade with this load. The reasoning for this will be better understood later on. You have all probably seen motors that you suspected gave a small return for the amount of current they took. Improper proportions and overwork produce wasteful effects. How this came about is partially explained by returning to the steam engine. Suppose we have a locomotive working 300 revolutions per minute, developing 200-horse power when taking steam full stroke. Let us overload her as in the case of starting so that her drivers can only make 20 revolutions per minute under full head of steam. The result is, she is actually developing less than 15-horse power. Does it not seem strange to you at this late day that nothing has been devised to overcome this? The same conditions and some worse ones govern electric motors; and it will be well to explain them here. There is a medium in all things. There is a limit to the saturation of magnetism. For instance, an iron bar surrounded by a coil of wire in an electrical circuit produces a certain magnetic effect. Doubling the amount of wire and current does not give you double the magnetism. The second coil is necessarily longer and offers more resistance to the current. Its effects are weaker on the iron core. So you will readily see, for high efficiency for a given amount of power, the question of proportions plays an important part. To analyze the necessity for another precaution, just return to the

Theory of the Dynamo.

You will remember the movement of the loops of wire in the armature were resisted by the field magnets, and Lenz's law shows us that the current induced was in such a direction as to oppose the initial force. We have seen that loops of wire revolving before magnets induced a current in the wires, and that an electric motor is constructed the same as the dynamo. It is obvious that the motor's armature revolving under the magnetic field must produce a current, and one in such a direction as to oppose the initial force. In other words, the current generated by the motor presses back against that which comes from the generator. This is what we call back electric motive force. The electro motive force of all machines is directly in proportion to the armature speed. Now you will observe that when a motor is allowed to run very fast it takes but little current, because the back pressure is nearly equal to the initial. But, if its speed is choked down so that it gives but little back pressure, it is taking an abnormal current and working very inefficiently, and also endangering the insulation of the machine. This is the

Principal Cause of Burning Out Armatures.

To avoid these objections, both in locomotives and motors, has been a hobby with me for many years, and it affords me much pleasure to assure your society that I have done it in a thoroughly scientific and practicable manner. The secret of it is to always let the machine work at an efficient rate of speed, irrespective of the speed of the cars. While a description of the apparatus might be of interest, it is outside of the scope of this paper to refer again to locomotives. Scientists, who have carefully studied the correlation of forces, tell us that in the best steam-engine practice they do not transfer 10 per cent of the energy of the coal into useful work. It is a well-known fact that electric motors are made to-day that transfer 90 per cent of the energy put into them. An increase or gain of 10 per cent more would be perpetual motion, and put its inventor on a level with his Creator. Although perfection has never been reached with any form of machinery, there is but little room for improvement in the

Modern Dynamo and Motor.

While this is not suggestive of encouragement to aspiring scientists, it points out another problem worthy of their study—that is, to turn the energy of coal directly into electricity, without wasting the most of it, as is the case in the transformation through the medium of steam engines. A single thought and a drop of ink have sometimes made millions think. Who knows but that it remains for some member of the "California Electrical Society" to solve this problem? So far, comparisons have been made with steam motors only. I will now turn to cable railways. Californians are proud of their magnificent cable systems, proud of the achievements of their engineers. The names of Hallidie, Root and others will pass into history, and their work will live long after them. It is not probable that the present generation will see anything better adapted for climbing hard grades than the cable system, principally for these reasons:

First—Cable cars descending grades assist others up. I am aware that this same claim is made for electric motors, and although I have worked on the problem and patented devices to accomplish it, much remains to be done before it can have practical application.

Second—An electric motor of reasonable weight and efficiency would necessarily do this heavy work at an expense of time. To average the same speed, they would be compelled to go up the hard grades slow, and down fast. Those considerations are strongly in favor of cable roads.

We will now turn to the other side. A few years ago, if a man wanted to ring a bell or

Make a Signal at a Distance,

He pulled a cable or wire. The entire mass moved and the signal responded. To-day we press a button, the mass remains stationary, but the bell responds. In one case, a large percentage of the energy was spent in moving the mass. Those same principles govern the two railroad systems of to-day. I am told by excellent authority that the loss in conversion with the cable on the Market-street line here is about 33 per cent. On the other hand, we have the authority of President Holmes of the Chicago cable roads and some prominent street-railway engineers that their loss on level track is about 83 per cent; that is, 83 per cent of the power of the stationary engines is used to move the cable and machinery, and but 17 per cent to move the cars and passengers. The discrepancy may partially be accounted for in this way: The Market-street cars run about one block apart. The Chicago State-street line about three blocks apart. Let us assume that the Market-street engines develop 800-horse power when moving 30 trains; also that it takes 400-horse power to move the cable and machinery without the cars. This would show a loss of but 50 per cent. Now let us assume they run the cars two blocks apart. Then this engine would be doing the work at a loss of 66 per cent. This reasoning brings us to the following conclusions: To get a high return for the amount of fuel consumed on cable railways, you must tax the cable and run the cars less than one minute apart. The roads in the world that require this close service are few and scattering.

In an Electric Road the Power the Engine Develops

Is directly in proportion to the work being done, whether 1 or 50 cars are in the circuit—always provided the wires have proper current-carrying capacity. While I fully recognize the importance of regularity in the speed of machinery, the conditions on street railways prevent this. If a car is passing through a crowded thoroughfare, it must run slow. On the other hand, the lost time should be made up by faster speed when the track is clear. This is readily done with an electric motor, and not possible with the cable cars. Electric motors can take their current from conductors in conduits, or from light wires overhead. Conduits mean two open expensive sewers the entire length of the line. Their construction should be avoided for sanitary considerations if for no other. The comparative convenience, cost of construction, cost of maintenance and operation being so largely in favor of electric roads is proof conclusive that they will be generally adopted. It means also that they will be more profitable to their owners and the public will ultimately be benefited by improved service or cheaper transportation. In reviewing this paper, I find

Many Items of Interest

Untouched. With your kind indulgence I will briefly refer to a few of them. I am told that Mathias Baldwin, founder of the celebrated locomotive works, was haunted all his life with the idea that locomotives should have rotary instead of reciprocating engines. The reasons for this are, first, the locomotive is necessarily top-heavy. When it leaves the rail it is almost certain to tip over. Again, it is impossible to put them on running balance. To better understand this, suppose we were to support a locomotive on its frame, leaving the drivers to revolve freely, and give her steam. She would immediately commence a rocking motion, and the tendency to leave her foundation would increase as the square of her speed. While this tendency might not be very great at a speed of ten miles an hour, it would be four times as great at double the speed. This obstacle has been thoroughly investigated and demonstrated by Mr. McLeoud, engineer of tests of the Pennsylvania railway. He estimates that with some of the latest designs the locomotives, when running at high speed, are delivering trip-hammer blows on the rail equal to a force of 60 tons at each revolution of the drivers.

Electric Motors are Rotary Engines

And entirely avoid this dangerous and injurious effect. For some time past the engineers of the New York elevated roads have been battling with the problem of how to increase the carrying capacity of their roads to meet the anticipated increase of business. The structure will not stand heavier locomotives, and the centrifugal force from the unbalanced parts of their locomotives precludes a higher rate of speed. When the exigencies of the times require improvements, the right man generally comes to the front. Mr. Leo Daft, one of the early workers in the field, steps forward and demonstrates the ability of a light electric motor to handle eight coaches, or double the weight of the ordinary train. What is the limit to

The Transmission of Power

Through the aid of electricity and the speed at which trains may be run? I am dazed at the thought. The wildest dreams of Jules Verne and Stockton are not wholly without reason, and are backed up with some correct theories. A few years ago the late Charles Siemens, to whom the development of electric science owes so much, expressed it as his opinion that a large percentage of the enormous power of Niagara Falls might be transferred through this agency and utilized for manufacturing purposes in New York City. Sir William Thompson, England's greatest electrical scientist, calculated that it is theoretically possible to transmit 26,000-horse power a distance of 300 miles through a copper cable one-half an inch in diameter, at a loss of but 20 per cent. Those suggestions, when made, were ridiculed by the public, but charitably considered by prominent electricians and apologized for as coming from sensational enthusiasts. The electrical pressure proposed was considered uncontrollable.

Within the last few months the principal electric-light company in London, desiring to distribute their light over a large area through small wires, decided to use this same pressure. About 40 years ago some members of Congress missed re-election because they were hoodwinked into voting to squander the people's money to aid Morse in demonstrating the telegraph system. Later came the telephone, first a scientific toy, then gradually coming into general use. Then the electric light, and to-day the motor is coming forward with its velvety motion, and will probably be here before some of our readers think of the subject again.

A MISSISSIPPI MYSTERY.—It is seriously told that "the length of the Mississippi river has always been placed at 4100 miles, but civil engineers familiar with the stream say that it has shortened itself over 400 miles in 20 years, and will do as well in the 20 to come." But we are not told whether that great river is straightening itself out from its snake-like curves, or whether the late severe winters along its northern course are the cause of its mysterious contraction. Cold is a great contractor.

Herschel's Weather Table.

For Foretelling the Weather, Throughout All the Lunations of Each Year, Forever.

This table and the accompanying remarks are the result of many years' actual observation, the whole being constructed on a due consideration of the attraction of the Sun and Moon, in their several positions respecting the Earth, and will, by simple inspection, show the observer what kind of weather will most probably follow the entrance of the Moon into any of its quarters, and that so near the truth as to be seldom or never found to fail.

If the New Moon, First Quarter, Full Moon, or Last Quarter happens	*IN SUMMER.*	*IN WINTER.*
Between midnight and 2 o'clock.	Fair	Frost unless wind Southwest.
" 2 and 4 morning	Cold and showers	Snow and stormy.
" 4 and 6 "	Rain	Rain.
" 6 and 8 "	Wind and rain	Stormy.
" 8 and 10 "	Changeable	Cold rain if wind West, snow if East.
" 10 and 12 "	Frequent showers	Cold and high wind.
" 12 and 2 afternoon	Very rainy	Snow or rain.
" 2 and 4 "	Changeable	Fair and mild.
" 4 and 6 "	Fair	Fair.
" 6 and 8 "	Fair if wind Northwest	Fair and frosty if wind North or N. E.
" 8 and 10 "	Rainy if South or Southwest	Rain or snow if South or Southwest.
" 10 and midnight	Fair	Fair and frosty.

OBSERVATIONS.—1. The nearer the time of the Moon's change, first quarter, full and last quarter are to *midnight*, the fairer will be the weather during the next seven days.

2. The space for this calculation occupies from ten at night till two next morning.

3. The nearer to *midday* or *noon* the phases of the moon happen, the more foul or wet weather may be expected during the next seven days.

4. The space for this calculation occupies from ten in the forenoon to two in the afternoon. These observations refer principally to the Summer, though they affect Spring and Autumn nearly in the same ratio.

5. The Moon's change, first quarter, full and last quarter, happening during six of the afternoon hours, *i. e.*, from four to ten, may be followed by fair weather; but this is mostly dependent on the *wind*, as is noted in the table.

6. Though the weather, from a variety of irregular causes, is more uncertain in the latter part of Autumn, the whole of Winter and the beginning of Spring, yet in the main the above observations will apply to those periods also.

7. To prognosticate correctly, especially in those cases where the *wind* is concerned, the observer should be within sight of a good *vane*, where the four cardinal points of the heavens are correctly placed.

Passing Events.

There is great excitement in San Diego and thereabout concerning quartz and placer mines 58 miles inland from Ensenada, Lower California. Many people from Ensenada have gone to the new fields. Lower California gold-mining excitements are somewhat frequent, and it is to be hoped that this will turn out better than its predecessors.

The Newberry-Vanton process, which has been quite successful in Australia, is to be introduced in Grass Valley for working gold ores. Large works have previously been established at Denver, Col.

The Senate Committee on Mines and Mining has reported in favor of amending the Alien Land law so as to allow aliens to invest in mineral lands on their own individual responsibility. This will be good news to miners in the Territories, as it is highly probable, after this report, that the law will be amended in accordance with it.

The last of the large castings for the hull of the new cruiser San Francisco has been made at the Pacific Rolling-Mills. The casting is of steel and in the shape of an enormous L, and is the port strut or hanger for the port shaft of the vessel, which is to be a twin-screw steamer. The charge of metal in the furnace was 26,000 pounds, and the strut will weigh about 16,000 pounds. About 12 hours of heating in the furnace at a temperature of 4000 degrees were required to bring the metal to the necessary condition for casting.

Mexican Mine Labor.

As a mining enterprise is so quickly affected by the price of labor, it would seem as though Mexico, with its low-priced labor, was *the* country in which a mining enterprise should flourish; yet those who have had some years of experience with labor at $4 per day in "the States" find that the cheap labor of Mexico is to-day really more expensive than the high-priced labor in this country.

The root of the evil in Mexico is custom; and the objectionable customs can generally be traced back to the "peon system," when the rule was task work.

In the time of the Spaniards powder could only be bought and sold by privileged persons, the lower classes not being permitted to have any in their possession; hence in the mine the drilling was done by one party and the blasting by another. This led to the "task" in drilling.

Custom has laid down the law that the miner shall not move his waste; this must be done by a "peon" at 37½ cents per day. In the olden time every one had to be watched, so to-day will be found on a well-regulated Mexican property every outside door with its velador (guard) and a guards, this or that, for every thing movable. When the wages paid are aggregated, it will be found that good skilled miners at $4 per day would really be cheaper.

It will always be found preferable to let the work on contract, except there be special reasons for day's pay, at so much per meter, the miners furnishing supplies, etc.

Even on contract work one meets with disappointment; eight men will take a contract—working four on a shift. One would expect the men, under average circumstances, to square at least two feet per day. After an experience of six months in good average ground (limestone and vein quartz) a friend of ours found that the best record was 1.9 meters for six days, or a trifle over one foot in 24 hours for eight men. This work was in ground that in the limestone districts in the United States would have been considered easy.

The cause for this trifling amount of work is a lack of knowledge of the proper use of tools and explosives. The men will arrange to blow out a pot-hole in the center of the breast, and then they will put in straight holes around this to square the work. In fact, it may be said that the work is "plugged" out. It is very rare that a hole is put in more than 18 inches deep or an effective rake given.

The cause for this character of work is: First, the powder. The product of the country, which is generally used, compares to the black powder of American work about as our black powder compares to a No. 1 nitro-glycerine powder. This, of course, does not permit of putting in deep holes. Second, the lack of a proper pitch or rake to the holes so as to get the best results. This can probably be traced back to the time when the drill-holes were "churned" in; the long drills necessary for churning in the cramped space precluding the possibility of giving much of a rake to the holes.

The miners of the present day have simply copied the practice of their ancestors; although they have had the great advantage of using hammers instead of churning in the holes, they do not seem to have profited by it to any great extent.

The average Mexican is very conservative, and cherishes the precepts laid down by his ancestors. Any foreigner who goes to the country with the idea that he "knows it all," and with the intention of running the country to suit himself, generally "gets left."

As a rule, the miners are good workers and fairly intelligent, and it has been observed that the minimum amount of work is due rather to a lack of knowledge than to a lack of effort.

The policy to pursue to remedy the faults is one of moral suasion until the men get thorough confidence in the manager—then command. Until he has the confidence of the men, he should never make any changes or institute new practices unless he is thoroughly sure of succeeding. The lower class of Mexicans have a great regard for power, and once convince them that you thoroughly understand your business, all you have to do is to lead and they will follow.

Operations of the Copper Syndicate.

During the past year the copper trade has been practically controlled by the French syndicate, which was formed in October, 1887, to force up the price of copper, in order to enhance the value of the large quantity of shares of the Spanish copper-mining companies held in Paris. Encouraged by the success of their first operations, and the facility with which they were enabled by the purchase of some 30,000 tons of Chili bars for immediate and forward delivery—the whole stock on Dec. 31st being only about 31,000 tons—to raise their value from £40 to £85 per ton, and that of the shares of the Spanish companies nearly 150 per cent, the syndicate determined to try and maintain values at the level to which they had raised them.

With this object in view they entered into negotiations with the leading copper-producing companies for the purchase of their total output for a period of three years, at a fixed price in some cases, and at a fixed price with a division of any excess realized in others. Ultimately contracts were concluded with the principal American companies, the three Spanish companies, the two Cape companies, and several of the smaller producers elsewhere. The price to be paid by the syndicate appears from the annual reports of the companies interested, and other sources of information, to be as follows:

Thirteen cents per pound (£61 10s. per ton, less 2½ per cent discount) with one-half of an excess realized, to the Lake Superior companies, the Parrott Co. of Montana, and the Arizona companies.

Twelve cents per pound of copper in the matte, equal to 13 cents per pound of refined copper, to the Boston-Montana, for 45,000 tons of copper, deliverable over three years.

Twelve cents per pound of copper in the matte to the Anaconda Co. for their first six months' production and 15 cents per pound for the second six months, an average of 13½ cents per pound, or 14½ cents per pound, equal to £68 10s per ton, with 2½ per cent discount per ton of refined copper.

Thirteen shillings per unit for precip'tate and 12s 9d for ore, or the equivalent of £70 per ton for the best-selected copper, to the Rio Tinto, Tharses, Mason & Berry, Quebrada, Cape, Namaqua and other companies.

The production of some mines is limited, that of others is allowed an annual increase, and on others no limit is placed. The quantity of copper contracted for and received by the syndicate during the past year is estimated by James Lewis & Sons of Liverpool, from whose report we obtain these figures, at about 160,000 tons, out of a total world's production of 260,000 tons. In addition to this, they have taken over from the Societe de Metaux and purchased in open market, at an average cost of about £72 per ton, 60,000 tons of Chili, in addition to about 12,000 tons of other copper, the result being that they now find themselves with a stock on hand of fully 145,000 tons.

The total purchases and sales of the syndicate for the year 1888 were estimated by the same authority approximately as follows:

PURCHASES.

56,000	Tons	Lake, Montana, and Arizona copper, at £61 10s. per ton, and half the excess realized.....	£3,444,000
9 000	"	Boston Montana matte, at £61 10s per ton	553,500
28,000	"	Anaconda Co.'s matte, at £68 10s per ton of refined copper.....	1,918,000
67,000	"	Spanish, Cape, Australian, Quebrada, Newfoundland, Panuncillo (Chili), Norwegian, Italian, Mexican, Japan, and other copper, at £70 per ton of refined copper.....	4,690,000
60,000	"	Chili bars, at £72 per ton (exclusive of interest, etc).....	4,320,000
12,000	"	Good merchantable copper, at £77 per ton.....	924,000
232,000	Tons	Costing.....	£15,349,500
		Add interest, commission, brokerage, etc.....	500,000
Total			£16,349,500

SALES.

38,000	Tons	Lake, Arizona and Parrott copper, at £70 per ton (say 16½ cents less half the excess over 13 cents).....	£2,660,000
7,000	"	Anaconda Co.'s matte sold in England at average of 15s. per unit, or £80 for B. S. (11,000 tons remaining in stock 31st December)	560,000
10,000	"	Anaconda Co.'s matte sold in United States at 15½ cents, or £73 5s. per ton.....	732,500
32,000	"	Other copper, at £80 per ton, average of best selected.....	2,560,000
87,000	Tons	Sold for.....	£6,512,500

A greatly increased production has resulted from the operations of the syndicate, but this cannot be deemed excessive considering the high price; but what has surprised the trade is the great falling off in the deliveries of copper, pointing to a diminished consumption of 37,478 tons in England and France. Smelters and consumers hold little, however. One of the disadvantages the syndicate labor under is that they have to carry the stock of copper usually held by the trade.

The success of the syndicate operations will mainly depend upon the extent of supply and demand during the present year. Unless some steps are taken to further restrict the output of those companies that have already contracted with the syndicate, there seems every probability of a further increase in the production of the world of 40,000 tons, bringing up the total for 1889 to 300,000 tons. On the other hand, there is little doubt that the consumption of imported copper will be considerably greater than during the past year, and will probably exceed that of 1888 to an equal extent, the supplies of old copper on hand being now exhausted, the tonnage of steamships in course of construction being 85 per cent more than 12 months ago, trade generally having improved and the use of electricity promising to be greatly extended; while India and other consuming countries will ere long require to replenish their stocks. Even with this, however, and in view of the extensive substitution of other metals for copper, in consequence of its greatly enhanced cost, there promises to be an increase in the stocks held by the syndicate in England, France and the United States during 1889 equal to that of 1888, or of nearly 100,000 tons, making the total about 245,000 tons. Whether the syndicate will succeed in obtaining a diminution of production, which it would appear to be the interest of the large producing companies to agree to, or will be able to bear the severe financial strain entailed by the carrying of so large a quantity and value of copper, remains to be seen.

Dynamite Guns.

The success which has attended the experiments with pneumatic dynamite guns is such that they are expected to greatly change the systems of coast defense and modern warfare. The U. S. Senate has passed the Army Appropriation bill substantially as reported by the committee, after adopting an amendment offered by Stewart, providing for the purchase by the Secretary of War of three pneumatic dynamite guns, with accompanying machinery, to be mounted on the Pacific Coast, at a cost of $187,500.

There are several forms of these guns for throwing dynamite, the principal ones being those of Graydon and Zalinsky. Lieutenant Graydon, late of the U. S. Navy, has an invention which consists in firing dynamite shells from modern guns or cannon, with the full service charge of powder and with no danger from heat or shock, at the same time securing the entire range desired and the complete penetration of the target by the shell before the dynamite is exploded, the penetration being necessary in order to obtain the full destructive power of the explosive. Several demonstrations of the invention have been made by U. S. Army officers. The explosive is prepared in a peculiar way.

The idea of projecting shells by compressed air was first worked out by Mr. Mefford of Ohio, who constructed a gun and had it tried at Fort Lafayette in 1884. The task of experimenting was left to Lieut. Zalinsky of the Fifth Artillery, who improved and perfected it and the projectiles in all their details. The 15-inch guns lately made throw 600 pounds of blasting gelatine. An eight-inch gun throws a shell containing 100 pounds of explosive a distance of 3000 yards, with an elevation of 33 degrees and a pressure of 1000 pounds. The air reservoirs consist of wrought-iron tubes on the traversing platform, which are connected with the air-valve on the gun. The U. S. Government has made elaborate experiments with this pneumatic gun and built a cruiser especially to carry them. This is the form of gun referred to in the U. S. Senate and which it is intended to purchase for use on the Pacific Coast. The gun is very long, those used on the cruiser being 40 feet. The gun fires fore and aft and is directed by steering the vessel. The electric fuse used in the shell is a marvel of ingenuity and acts with great precision.

IONE is developing a quarry of red sandstone of fine quality for building purposes.

New Chlorination Works.

Cheap Handling of Low-Grade Material.

There are in portions of this State large bodies of gold tailings which still contain much precious metal in such a condition that the amalgamation process would not save it. More of the same kind of tailings are being made every day. Works have recently been built in the northern part of the State, especially designed to beneficiate this class of material, and have been for the past few months working over gold-ore tailings of low grade.

"The Butters Ore Milling Works" are located at Kennett, 17½ miles north of Redding, Shasta Co., Cal., on the line of the California & Oregon railroad, and on the banks of the Sacramento one mile below the mouth of the Pitt river. The roasting and chlorination departments of the works are now in operation.

The design of the builder is to establish reduction works for the gold, silver and copper sulphide ores of this portion of the State. The location possesses natural metallurgical advantages in that it has behind it the water-power of Big Backbone creek, with a water-power of 1000 inches, running the year round under a head of 150 feet, thus giving ample power. Wood for all time can be floated down the Pitt to the boom at the works. The railroad at the door brings in ore and supplies, and the surrounding country is well known for its abundance of low-grade sulphide ore.

The first ditch, for 200 inches of water, is now under construction and about two-thirds finished, and the works now completed are ready for handling crushed materials, such as concentrates from vanners or blankets, crushed ores, tailings, etc.

The works consist of a roasting-house containing a reverberatory furnace 43 feet long outside and 12 feet 3 inches wide, containing 3 hearths each 10 feet square, a dust-chamber and two alternating cooling pits for chlorination on cooling floor. The lixiviation-house contains two ore-tanks each 14 feet diameter and 5 feet high, with a capacity of 20 tons to each tank. The tanks have counterbalanced lids fitting in water channels on the outer edge of tank for use when chlorine gas is used The two precipitation-tanks are 10 feet in diameter and 6 feet high, and the lower or copper precipitation-tanks are 12 feet in diameter and 4 feet high. The tanks and foundations are all built on inclined water-tight floors leading to waste-tanks. The generator for the production of chlorine is a very satisfactory machine made after designs of the builder to run by power and heated directly by a wood fire, being practically a lead-lined kettle of 120 gallons capacity, arranged with valves and safety overflows, the connections with the vats being made with water-stopped lead valves, no hose being used in the works. The laboratories, melting-rooms, shops, offices, living apartments and stables are very complete and compact. The bricks, tanks, lead and iron work were all worked up and manufactured on the spot, the iron castings alone being brought from San Francisco, making these works as they stand not only the most recent, but undoubtedly the model gold chlorination works on the coast.

They are now handling 1000 tons of gold tailings assaying from $4 to $6 per ton, at a cost of about $1.75 to $2 per ton by the chlorination process; these tailings are located at the Central mine, on the line of the railroad 12 miles below.

The fact that such low-grade material, in which not a trace of free gold is visible, and from which but 30 cents per ton, even after roasting, can be obtained by amalgamation, can be treated by the chlorination process at a profit, is one that, to say the least, deserves notice. The capacity of these works is from 300 to 400 tons per month of their kind of material, of which only about one-tenth is roasted.

The builder and owner, Mr. Chas. Butters, who built the large chlorination works of the San Sebastian Gold Mining Company of San Salvador, the largest works of the kind on this continent, conducts a regular assaying and ore-testing business, charging $1 per assay, and is prepared to purchase tailings or crushed stuff, or to work such material for certain fixed charges, from $3 to $18 per ton, depending on the material, and from 80 to 90 per cent will be returned. The railroad company is making very liberal rates on such low-grade material, which can be shipped in bulk without the use of sacks.

PUEBLO, Colorado, has just had a Mardi Gras celebration, which was largely attended. In the evening there was a grand procession. The Mardi Gras floats, 12 in number, were very beautiful and carried Rex and his queen and suite. They all carried out the sentiment of Pueblo's future greatness, each typifying one of the minerals produced at Pueblo's Smelting Works. They were followed by a long line of floats and trucks prepared by business men and manufacturing firms representing Pueblo's industries and exhibiting innumerable ingenious and interesting devices. The pageant was a credit to Pueblo and to Colorado, being the first affair of the kind ever attempted west of St. Louis. The idea of the mineral floats was especially unique and appropriate.

CHEMICAL LECTURE NOTES.—John Wiley & Sons have just published a volume with this title, by Prof. P. T. Austen, professor of general and applied chemistry, Rutgers college and New Jersey State Scientific school. This little book is not intended to be a text-book of chemistry, but is simply a collection of notes and observations on certain topics which experience as a teacher has shown the author often give the student more or less trouble. No particular order has been observed in the arrangement of the topics, nor has any attempt been made to include all the rocks and shea's on which the chemical student may get wrecked. The subjects considered will prove of interest and value to all thoughtful students.

Freeman's Dry-Gold Separator.

(*Continued from page 145.*)

duced by the expansion of air. The close mesh of the apron retains the air within the air chest until it becomes compressed, and the expansion of the air forces it through the apron; when, becoming liberated, it resumes its original space and all force is destroyed. The action of the air in this machine is wholly by expansion and not by velocity, and there is no blast to drive the gold from the riffles. The force of the current at the surface of the apron is strong enough to buoy up stones of considerable size and carry them off from the apron; but immediately it reaches the open air, it becomes dispersed and its force is lost. The great specific gravity of the gold allows it to lay on the apron undisturbed by a current that will float the rock and debris off.

A small prospecting machine, weighing only 27 pounds, is also made, which is similar to the larger in construction and has a capacity of two tons a day. It is provided with straps for carrying on the back. The same inventor has a pulverizer for clay and cement which cleans from the stone all the particles attached, thereby liberating the gold and preparing the gravel for thorough separation. The separator has also a "blacksmith" attachment, as shown in the cut The price of the 50-ton machine is $125; the 100-ton machine, $200; the prospecting machine, $25; and the blacksmith forge $8. Mr. Freeman has a number of testimonials from people who have used his separator. The address is J. B. Freeman, Los Angeles, Cal.

SETH COOK, the well-known mining operator, died at the Palace hotel on Tuesday last. He has been identified with the mining interests of California and Nevada for many years and leaves a fortune valued at from two to three millions of dollars. Though latterly not very robust, Mr. Cook's death was altogether unexpected even by his most intimate associates.

THE DOBRIANSKY FURNACE.

The Dobriansky Furnace.

In last week's PRESS we gave the observations of F. L. Garrison on the metallurgical appliances of the iron works at Dobriansky, Prussia, and the Wartsilla Iron Works, Finland. On this page are cuts of the Dobriansky furnace. The first furnace designed for the use of hard refractory ores, and to make loupe capable of being directly hammered and rolled without further refining, was started June, 1886, in Count Stroganoff's Iron Works at Dobriansky, in the Ural, and has given great satisfaction ever since. It was originally intended to build two furnaces, 35 feet in hight, 9 feet of which was for gas "take-off." In order to facilitate the building, however, it was determined to build only one stack. This resulted in a furnace 26 feet high from the top of the movable hearth to the throat, having a diameter of five feet at the belly and four feet at the throat. The inner and outer shells are separated by a space of seven inches.

The tendency of the unreduced iron to stick to the lower portion of the furnace was ingeniously overcome by inserting into the lowest part of the stack a hollow cast-iron ring, with its upper edge concentric with, but somewhat less in diameter than, the inner shell, and extending downward, gradually acquiring a quadratic shape, with rounded edges. The outer shell of the furnace is supported upon flanges, with which this ring is provided. The blast passing through the hollow walls of the furnace is conducted to and passed through this hollow ring by means of two broad flat tubes, situated on opposite sides of the furnace. By this arrangement it is easy to repair the parts of the furnace exposed to a high temperature; and by thus keeping the walls cool at this place, the unreduced iron seldom, if ever, sticks to them. At the same time the temperature of the blast is increased.

The inner wall of the furnace is lined with bricks made of "chamotte," 1½ to 2 inches thick, for a hight of 5 feet above the upper edge of the cast-iron ring. The upper part of the stack, as well as the cast-iron ring and the hearth, are without any lining. The stack is supported by four pillars made of steel rails fastened together and inserted into cast-iron sockets, the upper ones being fastened to the outer shell of the furnace, and the lower to an iron bed-plate. This bed-plate rests on a foundation of ordinary brick 2½ feet high, in which two channels are made, crossing each other at right angles, thus giving access for the slag-car to be run under the hearth, and also room for the apparatus to raise and lower the hearth. The cuts in Mr. Garrison's paper, though lettered, are not described in detail, but are sufficiently clear to be properly understood.

The carbonization of the reduced iron can also be regulated by the ore charges and the quantity and temperature of the blast. The furnace may be so operated that soft iron or steel can be produced as desired, the only difference in the operation being that in the former case the ore charges are larger. If hard iron or steel is desired, the temperature in the lower part of the furnace must be increased, and the inclination of the blast into the hearth decreased. The charcoal used at Dobriansky is very inferior, being made mostly from Siberian fir, which produces a porous, friable charcoal, hardly capable of sustaining the weight of the charges. It is usually made in meilers, but badly done, and contains a large amount of moisture.

ON Saturday U. S. Treasurer Hyatt received at Washington from the Philadelphia mint two million standard silver dollars, weighing 60 tons. This is the largest single shipment of silver ever known, and required six express cars to carry it. This shipment fills the new vault in the treasury to its utmost capacity, $86,000,000 being there. Besides this amount, the treasury also holds 1900 tons more, making 4500 tons of silver on hand, or about $150,000,000.

ON Tuesday the roving exhibit of the State Board of Trade was in Toledo, Ohio, and a dispatch to the secretary stated that the number of visitors was almost beyond computation. So far, during the two months that the exhibit has been on the road, about 200,000 persons have passed through the cars, and the result has been perceptible in the increased demand for California products wherever it has tarried.

MECHANICAL PROGRESS.

Cast Steel vs. Built-Up Guns.

Much interest is being taken in the experiments which are now being made in regard to the relative effective of cast steel and "built-up" guns. We have already in past issues given the result of the trial of the Hainsworth cast-steel gun, which, although a decided failure, is thought not to have failed through any imperfection in the principle upon which the gun was manufactured, but through a fault in its after-manipulation.

As a proof that the principle of cast-steel guns is not a failure, we have the trial, just completed, of a six inch steel gun cast at the Standard Steel Casting Co.'s works, at Thurlow, Pa., which has been successfully made at the Government proving grounds at Annapolis with 12 rounds, with the full charge of 48½ pounds of prismatic powder and a 100-pound projectile. In this gun the steel was made by the open-hearth process, while the one that burst a few weeks since at the first round was of Bessemer steel.

The *Iron Age* in speaking of this test says: "While the test must be a most gratifying one to the makers of the gun and to those who have insisted that a solid steel gun can be made that will stand all of the tests and more than are required from built-up guns, it by no means settles the question between cast guns and built-up guns. The superiority of the cast gun, if it is superior, as we believe, to the built-up gun, can only be decided as the result of a number of tests. The results with built-up guns are not such as to justify the claim that is made for them on the score of strength. We have already given in our columns proof of the great liability of these guns to burst, but there is an impression in their favor, and to remove this impression and give the cast gun a standing will require more and more severe tests than that to which the Thurlow gun has been subjected. We are firm in the belief that we have expressed for years in these columns that the cast gun can be made a better gun than the built-up gun. We do not yet claim that the guns made prove this; in fact, there are but two guns upon which we can rely for evidence, but those who know the character and possibilities of steel and the requirements for guns as well, possibly, as any one the world over, still insist, notwithstanding the failure of the Hainsworth gun, that the cast gun is a better gun than the built-up gun, and when the necessary experience in their manufacture has been attained, guns giving far better service than the built-up guns can be made of cast steel." The chief advantages of this mode of manufacturing guns of large caliber is the rapidity and cheapness with which they can be turned out.

IRREGULAR DISTRIBUTION OF SILICON IN PIG IRON.—Very few persons, even among quite well-informed workers in iron, we imagine, are aware of the great difference which exists in pig iron, from the same charge. The following from the *Iron Age*, in reference to this matter, will be noticed with interest: In analyzing samples taken from every other bed of a cast of pig iron, Mr. J. W. Thomas finds the silicon to vary considerably, the iron coming first from the furnace having the highest percentage of silicon. The following are the silicon results, beginning with the first bed that is filled:

First cast.		Second Cast.	
First bed	3.328	First bed	2.021
Third bed	2.058	Third bed	1.732
Fifth bed	1.800	Fifth bed	1.741
Seventh bed	1.800	Seventh bed	1.765
Ninth bed	1.834	Ninth bed	1.722
Eleventh bed	1.834	Eleventh bed	1.783
		Thirteenth bed	1.853

The percentage of silicon varies in each pig, being higher at the point of the pig than at the butt. This is shown by the following results:

	Point of pig.	Butt of same pig.
1	3.328	2.167
2	2.058	1.960
3	1.890	1.806
4	1.800	1.751
5	1.834	1.787

The data given above are from the last volume of the "Transactions" of the Iron and Steel Institute.

ELECTRIC MOTORS FOR CUTTING TREES.—It is sometimes inconvenient to drive saws for cutting trees by steam, especially in thick woods, and electric-power has recently been adopted in the Galician forests. The trunk is usually sawn by such machines, but in this case it is drilled. When the wood is of a soft nature, the drill has a sweeping motion and cuts into the trunk by means of cutting edges on its sides. The drill is actuated by an electric motor mounted on a carriage, which is brought up close to the tree and shackled to it. The motor is capable of turning round its vertical axis, and the drill is geared to it in such a manner that it can turn through an arc of a circle and make a sweeping cut into the trunk. The first cut made, the drill is advanced a few inches, and another section of the wood is removed in the same way until the trunk is half severed. It is then clamped to keep the cut from closing, and the operation is continued until it would be unsafe to go on. The remainder is finished by a hand-saw or an ax. The current is conveyed to the motor by insulated conduits brought through the forest from a generator placed in some convenient spot. A more direct method of cutting trees by electricity is that adopted some years ago, in America, we believe, where trunks were cut through very rapidly by a wire made red-hot by an electric current passed through it.—*London Iron.*

ENGLISH VS. AMERICAN LOCOMOTIVES—A TEST TRIAL.—The Pennsylvania Railroad Company has recently purchased for experimental purposes a superior English-built locomotive. This locomotive will be seen in contest with one of the best-constructed American-built locomotives. In order to make the trial perfectly fair, an English mechanic from the shops of the London & Northwestern Company, by which the engine was built, accompanied it to see that it was properly set up, and an engineer from the same was also imported to run it. The engine, which is thoroughly English in every particular, down to the absence of headlight and "cowcatcher," will afford a practical means of settling the much-mooted question as to the comparative superiority of English and American locomotives, as an opportunity will now for the first time be given for testing the two types under precisely the same conditions of climate, fuel, water, roadway, traffic and management. American locomotive builders and officers will await with much interest the results of the competition. The locomotive has already commenced its work upon the road.

MANGANESE STEEL FOR DRIVE CHAINS.—A new use has been found for Hadfield manganese steel, in the manufacture of drive chains for elevators. Mr. C. E. Hall of Sheffield makes a sewerage elevator in which he uses a novel application of his dredger. The machinery is to be employed for the clearing out of the residuum in the tanks at sewerage works. The dredger is driven by Mr. Hall's patent drive-chain. An interesting point in this connection is that Mr. Hall has designed his driving chain so that it can be made of Hadfield's patent manganese steel. We need scarcely point out the importance of this new departure in the manufacture of driving chains. Mr. Hall's is the only driving chain that can be made of manganese steel at the present time. One of the driving chains made of manganese steel has been at work at the Manvers main colliery for 12 months with excellent results. Large numbers of them are being made for gold, diamond and coal-mining operations in various parts of the world.—*Iron Age.*

AMERICAN MACHINERY IN DENMARK.—Mr. Ryder, the American Consul, writing from Copenhagen, says: "All articles of American machinery (agricultural) that have hitherto been introduced in this kingdom, continue to maintain their high reputation among the purchasing classes. They are found less heavy than English machines employed for similar purposes, and are of superior finish, being also of better material than those of German make." Mr. Ryder's qualification above of the "purchasing classes" indicates that the merchants and importers are not equally favorable to American machines, which is no doubt the fact. It is much more convenient to procure machines in either England or Germany, and the methods of business are better understood. The "purchasing classes" are, however, important factors in the case.

NAILS FROM SCRAP TIN.—Among the useful purposes to which scrap tin has recently been applied, is that of the manufacture of nails. For this purpose scraps of tin are cut by dies into rectangular bits, with a length of about three times their width. These scraps are then fed from an automatic hopper between dies, where they are squeezed first to square form, like a nail, then headed. Nails of this kind are well fitted for many purposes, being free from tendency to rust; also light, very rigid, and capable of being driven into the hardest wood without buckling.

IMPROVED WIRE FOR ELECTRICAL PURPOSES. A new process has been brought out in Vienna for the manufacture of copper-coated steel wire for electrical purposes. The old method was galvanic, while, according to the new one now proposed, the steel wire will be coated by spirally winding around it very thin copper bands. The object in all such wires is to combine the great conducting power of the copper with the tenacity of the steel.

THREE-CORNERED NAILS.—It is stated that a large plant for the manufacture of three-cornered wire nails will be established at Newcastle, Pa., at an early date. The company which proposes to engage in the manufacture of these nails is known as the Three-Cornered Wire Nail Company, and has its headquarters at Pittsburg. It is composed of J. C. Williams, William Taylor and other capitalists of the city.

STEEL as a substitute for granite blocks for paving streets is attracting considerable attention. Its durability and cheapness are claimed to be two strong points in its favor in most sections of the country, and tests of its efficiency are to be made during the present year.

LABOR-SAVING MACHINERY.—An English paper states that the modern labor-saving machinery introduced into foundries and machine-shops has resulted in 50 men producing as many castings as were formerly turned out by 200 men.

SCIENTIFIC PROGRESS.

The Laws of Storms.

Meteorologists are not yet agreed regarding the laws that govern the origin of storms. Storms of all kinds, whether they are called tornadoes, hurricanes, cyclones, or typhoons, present in a general way the same phenomena, that there is an area of light atmosphere, or low barometer, as it is called, toward which the air rushes from all sides to fill the vacuum, thus producing a whirling movement near the center. There is at the same time a motion forward in a given direction. The greater part of those who are within the range of a storm only feel the wind as blowing from a fixed quarter, especially when its diameter is great, and this may sometimes be 2000 miles. In the very center of a typhoon or cyclone there is a dead calm, which lasts but a few minutes, after which the object, be it a ship or village, finds itself in the midst of a conflict of the elements more terrible than ever. In this revolution of a storm around an upright axis the revolution is in the northern hemisphere from right to left, and in the southern hemisphere from left to right.

To understand a storm, it is always necessary to go back to first principles. Its origin is invariably near the equator, where, on account of the eastward movement of the earth, the winds have an apparent direction toward the west; but as the revolution of the surface of the earth north and south of the equator is less rapid, owing to its diminished diameter, as these air currents diverge therefrom they immediately take an apparent direction toward the east.

Given this law of air currents, it only remains to consider the great cause of storms, which is the unequal heating of the air over the earth's surface. Storms have their favorite routes of travel. No storm was ever known to travel from Boston to Philadelphia, from Chicago to St. Louis, or from Nashville to New Orleans; and when the word storm is used it means the storm center. Storms cross the Atlantic invariably from America to Europe and exhaust their force on the coasts of Great Britain and France, or not far in the interior. They never return by the same route.

When a large area of air near the surface of the earth has been heated to a high temperature, it rises, giving origin not only to the currents that rush in from all sides, but causing a mass of the colder air to fall from the upper strata of the atmosphere. It is principally this cold air falling from above that produces relief after a heated term, after a thunder-storm or during a hot summer night. People say after a summer shower, "The rain has cooled the air." This is a fallacy, for it is not the rain that cooled the air, but the cool air falling from the upper strata of the atmosphere, or in some cases coming from a cooler, northern latitude.

According to the theory of M. Faye, into an air vacuum at the surface of the earth falls one of the eddies already formed in the upper stratum of the atmosphere. The rotary motion increases in velocity as it descends, not only from causes inherent in itself, but because the conditions of the lower air are favorable to the propagation of the circular movement. Hence result the storms that are most terrible in their effects, such as the cyclones of the West, the cyclones of the Indian ocean, and the typhoons of the China seas. It would, perhaps, be too much to assert that were it not for these upper currents and eddies there would be no cyclones, for the lower stratum of atmosphere appears to contain all the conditions necessary to their formation; but it is certain now, as it always has been, that the descending currents produce violent complications.

Sailors assert that the wind blows in certain cases straight downward. They have not only felt it, but they say that it is the cause of that condition of the sea when the waves seem beaten flat upon its surface. It is useless to understand the nature of air currents and the cause of storms unless the knowledge assists in navigating the ocean, and in the protection of life and property by sea as well as on land. In this study of the weather it is pleasant to know that this country has always taken and still maintains the lead, simply because as a practical people we approach the subject from its practical side.—*S. F. Chronicle.*

A NEW ADULTERATION OF COFFEE.—Science seems to be aiding largely in the adulteration of food products when manipulated by unscrupulous hands. Of late, artificial coffee beans have been found in the European (German) markets. They are made from roasted grain flour with an addition of dextrine or some such body. There are two establishments at Koln which furnish the necessary outfit, with formula, etc., for the manufacture of the beans. According to an original letter from one of these establishments in the possession of Dr. A. Stutzer in Bonn, from 1000 to 1200 pounds of beans may be made in one day with the outfit, which the firm offers at a high price. The letter further predicts a golden future for the article, but advises that it be used for the adulteration of genuine coffee only in such countries where the laws are not very stringent, etc. These prospects must be very enticing to sophisticators, especially as the imitation is so perfect that only a very critical examination will serve to detect the adulteration. The artificial bean distinguishes itself from the genuine in being perfectly symmetrical and of the same size, and that the epidermal membrane is entirely wanting.

Contrast of Colors in Nature.

Nature is very sparing of showy contrasts of warm and cold colors. Red and blue are very rare, and of yellow and blue the cases are but few, and black and blue are found in lepidoptera more often than white and blue are seen in our flora or fauna. It is not uncommon for one of two strong colors to be overcast with a tinge of its fellow, or for both of them to be reconciled by a common touch of black or of some third color, or for one of them to be lightened by a dash of white, while the other is lowered by as much black, and so red, off-hued with black—russet and green upbrightened with white—often meet in the autumn in dead and dying patches of fading leaves. It may be shown, I believe, by the refractions of light in crystallized gypsum that brown is the complementary color to lavender-gray; and how true to herself is Nature we may go forth and see, in the fall of year, in the dead and curled leaves of the mugwort, or meadow sweet, which are beautiful even in their death, with one side brown and the other the brown-matching gray; and, if brambles be cut in the leaf-greeny season, their two surfaces soon wither into the harmony of gray and brown.

And what use are we to make of these hues of Nature? They are warrants for a gray mantle under locks of brown hair, or a brown bonnet or trimmings, or a gray room wall with brown furniture; and if, on a hot summer's day, I see the dark leaf shades playing on the gray bark of a young beech, I can boldly lay darkish leaf shades on a wall of the beech bark's hue; or if, after the winter rains, I find a barkless pole in railings, tinted with the palest blue-gray, and on breaking off a splinter of it I find its inner wood of its true color of pale brown-yellow, why should I not take the inner tint for my wall and the outer one for the skirting? Or, if I pick up a piece of lichen of dull green on one side and dull gray on the other, why should I not bind my book in one color and lay on it a lettering piece of the other? Nature is the best school of art, and of schools of art among men those are the best that are Nature's best interpreters.—*London Architect.*

A SUBSTITUTE FOR THE MARINERS' COMPASS. The London *Electrician* prints a singular rumor to the effect that the use of the compass is about to be altogether superseded. A method is said to have been discovered by which the true north may at any moment be ascertained by means of a device which is wholly independent of magnetic action. The reading is, however, obtained by electrical means, and it is said that a well-known Berlin firm of electricians has secured the patents. The informant also surmises that gyroscopic action is also involved.

ANOTHER NEW POWDER.—At the Royal Powder factory of Wettern, in Belgium, a new gunpowder is being made. They call it poudre-papier, or paper-powder, and it is said a charge of 2½ grammes (39 grains) gives, in a rifle of small caliber, an initial velocity of 660 yards to the ball. This is equal to, if it does not beat, the Lebel powder. The additional advantages are attributed to it of not smearing the barrel, of producing no smoke and of causing lit le recoil.

ELECTRIC EXPERIMENTS ON ANIMALS.—A party of scientific gentlemen recently performed a series of electrical experiments on the animals in a menagerie at Bridgeport, Conn. The baboon, the sea lion and seals, monkeys, the elephants and other animals were treated to doses of the electric current. All the animals, with the exception of the elephants, manifested an intense disgust at the experiments and fought and howled with rage. The elephants on the contrary, appeared to enjoy the electricity.

IMPORTANT MINERAL DISCOVERY.—The State Mining Bureau recently received a specimen of sulphide of bismuth carrying 2 per cent of silver. It comes from the eastern portion of Fresno county, and is the second sample of bismuth discovered in this State, the first one having been found in Inyo county. When it is considered that bismuth is quoted at $2.40 a pound, the importance of a correct diagnosis of the discovery is at once apparent.

ENGRAVING ON GLASS BY THE AID OF ELECTRICITY.—A process of engraving on glass and crystal by electricity has been communicated to the French Academy of Sciences by M. Plante. The plate to be engraved is covered with a concentrated solution of nitrate of potash and put in connection with one of the poles in the battery, and the design is traced out with a fine platinum point connected to the other pole.

ANOTHER TWENTY MILLIONS DEVOTED TO SCIENCE.—It is said that John D. Rockefeller, the millionaire head of the Standard Oil Co., is about to found a university, with an endowment of $20,000,000, either in Chicago or New York.

A CONVENIENT ALLOY.—An alloy which m lts at a lower temperature than the magic spoon does is obtained by melting together 48 parts bismuth, 31 of cadmium, 10 of lead, and 20 of zinc. This alloy melts at 135° F.

GOOD HEALTH.

Health of the State.

The report of the State Board of Health for the month of January has been issued, embracing returns from 68 cities and towns containing a population of 700,850.

The total number of deaths for the month was 992, or a percentage of 1.41 per thousand for the month, or a rate of 16.92 per thousand for the year. The percentage is slightly above the average, the increase being almost entirely due to the diseases affecting respiratory organs.

Consumption claimed 165 victims, an increase of 28 over the previous month. Pneumonia was unusually prevalent and fatal, 103 dying from it. Bronchitis numbered 34 cases. Diphtheria and croup were fatal in 43 cases, while scarlet fever claimed but 1 victim throughout the State for the month.

There were only 3 fatal cases of smallpox in this city and 1 in San Leandro.

Diphtheria seems to have a wide prevalence, but few localities being free from its ravages. The report recommends the most radical precautions against its spread. The following remarks which we condense from the report should be read and observed with care: The impression seems to be very general that the frequency of this disease is in the main dependent upon bad sewerage, defective drains, foul air, and insanitary conditions generally. Although these conditions may render the persons exposed to them more liable to take the disease from the deteriorating influence upon the general health, yet they do not *generate* diphtheria, nor is the disease capable of spontaneous generation any more than is smallpox or cholera. In order to produce diphtheria you must have the germ of the disease present, and then to be developed it must come in contact with a suitable soil for its growth. From this fact the inference is plain that although prudence requires that the sanitary condition of the patient's surroundings be kept in the best possible condition, and all predisposing causes which might deteriorate the patient's health be removed, it is infinitely more important to insist upon the complete isolation of those attacked, and the rapid destruction by fire of all substances likely to be the conveyancers of contagious germs. Diphtheria germs, as far as can be ascertained, are carried in the air, exhaled by the breath, deposited on the clothes, on the walls, everywhere in the room; hence the necessity for the most thorough disinfection of the person and the dwelling before intercourse with well persons is allowed. If more care was exercised in this regard we would hear less of the disease, and many very valuable lives saved that are now sacrificed by criminal carelessness, and the utter disregard for the public welfare.

Starving a Cold.

How it Can be Done Without Inconvenience to the Sufferers.

The man who originated the oft-quoted and unscientific maxim, "Feed a cold and starve a fever," either did not understand what he was writing about, or he has been widely misunderstood, to the great injury of multitudes who have acted on the absurd maxim. Presuming that the author of it was a physician, who knew something of the nature of a cold and the action of remedies, he must have spoken subjunctively, and not imperatively. And then it would read thus: If you stuff a cold the consequence will be that you will be thrown into a fever as the result of the stuffing treatment of the cold, and then you will have to starve the fever. This is a true and sensible interpretation of this commonly received maxim, which has done as much harm as any of the thousand and one of the popular errors which prevail on medical subjects.

If it cannot be explained in the manner mentioned, it must be remanded to the dark ages of ignorance and superstition, and classed with lunar and stellar influences over the human body, witchcraft and other absurdities long since exploded in the progress of true science. Without dwelling on the nature and causes of colds, or on what physicians call the pathology of these disorders, I will say that a low or even starvation diet for a few days, with the free drinking of warm, mildly stimulating teas, is better for a cold than any drug or combination of drugs. If with this a warm bath or a hot foot-bath is taken, little more will be needed. Nine cases in ten of colds can be broken up in this early stage by a hot-foot or rather leg-bath, keeping the bath as hot as it can be borne until perspiration arises. After the bath, drink a half-pint of hot lemonade and go to bed.—*Woman's Work.*

DRAUGHTS IN TRAINS.—Draughts encountered in railway traveling are the active causes of many intolerable attacks of neuralgia. Occasionally they have more permanent consequences. To avoid this peril, most persons try to secure places with their backs to the engine. This answers well enough as regards the seat next the window, but owing to the angle at which the air enters the rapidly advancing carriage when a window is open, the occupant of the seat, with his back to the engine, receives a reflected current of air, not so strong, but fully as likely to produce what is popularly called a "chill" as that to which the brave traveler who "likes air," and persists in riding forward, with the window down, exposes himself. The prudent man, who has ensconced himself in the second seat, and rides backward, probably finds a tingling in the ear nearest the window, and possibly suffers a mysterious attack of toothache or tic douloureux some days afterward. Any one interested in the subject may work out the conditions of this phenomenon with the aid of a pencil and the familiar law that angles of reflection are equal to angles of incidence. This simple circumstance seems to have been unaccountably overlooked.—*Lancet.*

Brick Residences Should be Painted.

Statistics show that people live longer in brick houses than in stone, and that wooden houses are the healthiest. This suggests the idea of using paint on masonry. An authority states that a hundred years ago it was fashionable to paint brick buildings white, and many charming old structures remain to attest the value of the coat of paint in preserving the masonry, and its pleasant, homelike effect is a foil to the vines and shrubs with which even city houses are now commonly adorned. If it should prove, as might be easily ascertained, that the painted brick houses preserve their inhabitants more effectually from sickness and premature death than the unpainted ones, it would be worth while to revive the ancient fashion, and, with our greater resources in the way of materials and ideas, exterior coloring might become as important an accessory to the architecture of the twentieth century as it was to that of the twelfth or thirteenth.

Painters who when bidding for jobs are expected to be responsible for the safety of the glasswork, do not like the plan. Years ago the custom of holding painters responsible for glasswork was much more general than it is at present. The presumption is that painters are unnecessarily careless, but this has but little foundation to stand upon. Following are a few lines concerning the painting that ought to be kept in mind: The best time to paint the out side of a house is early in the winter or in spring, when the air is dry and no dust is flying. Knots in boards may be killed before painting by several methods. The surest and best in fine work is to cover the knot with an oil size and lay silver leaf over it. Glue size mixed with red lead, or gutta-percha dissolved with ether, will satisfactorily cover knots not exposed to sunshine. The heat of the sun draws the pitch in the knot to the surface, through the paint. If woods to be painted are soiled by smoke or grease, those parts are to be washed with a solution of saltpeter in water, or with very thin lime whitewash. If soapsuds be used to wash off smoke or grease, the wood should be thoroughly rinsed with clean water, or the paint will not harden. The first, second and third coats of paint on the outside of buildings should be prepared by mixing the white lead with boiled linseed oil, and allowing each coat to dry hard before applying the next.

USEFUL INFORMATION.

Must the Piano Go?

It does seem as if the piano had reached about the end of its tether. Its compass, says a German journal, has been extended to the utmost acoustical limits, and it has been improved until there appears to be no more room for improvement. The virtuosi of the present day have attained, practically, perfection in execution, and the compositions of Chopin, Schumann, Liezt, Tausig and Rubinstein are as difficult as any music can be which is capable of being performed on the piano by a single pair of hands. Then what next? Nature abhors a vacuum and art abhors a halt. There is no use in doing over again what has been done already well enough. We must be original. We must advance. We must invent new lines or new ideas in composition, or else not compose at all. We must play better, or at least try to play better, than Rubi stein or Von Bulow or Joseffy, or else confess ourselves mere scioliats and imitators. This is the spirit of the true artist—of true art. But it is hard to see how there can be any further progress in piano music or piano playing. In this crisis, however, it is allowable to hope to see before long some new instrument no larger, no costlier, no harder to master, than the piano, which shall combine the string principle and the wind principle, and unite the best qualities of the piano and the organ—in other words, a miniature or microcosmic orchestra. Such an instrument would be unhampered by the great deficiency of the piano, which is an inability to sustain tones, or, rather, to sustain some tones while not sustaining others; and when such an instrument is invented there certainly will arise a new group of performers, altogether distinct from the present piano virtuosi, and musical composition will take a fresh start on a line of absolute novelty and originality.

THE AMERICAN WHALING BUSINESS.—The annual review of the American whale fishery shows that there are now 106 whaling vessels owned in this country, of which 20 are laid up at home. Prices for the products, except whalebone, have been low, and the right whaling in the Arctic ocean, where most whalebone is taken, is becoming more and more popular, so that now about half the total tonnage of whaling vessels is employed in that branch of the service. In the Arctic last summer there were 47 whalers, a slight increase from the year before, but their average catch was only about half that of 1887. Of the American whalers now in service, 63 are owned in New Bedford, 23 in San Francisco, 8 in Provincetown, 4 in Edgartown, 3 in Boston, 3 in New London and 2 in Stonington.

FASTING HORSES.—Doubtless it is the experiments of those fasting gentlemen, Dr. Tanner and M. Succi, that have led to experiments of short commons on horses. Trials have been quietly going on in some French fortresses, to ascertain how long artillery horses could hold out, when deprived of solid and liquid food; and of these two life sustaining necessaries, which was the more essential. It has been found that a horse can sustain life five times longer when not deprived of water than if deprived of all solid rations. A horse will not exist longer than five days if kept without water, though it may be abundantly supplied with solid food. Nor will a horse hold out if insufficiently furnished with water. It perishes because the stomach has been exhausted. In Algeria, where cavalry horses have to remain frequently two and three days during a campaign without water, they will, on arriving at the wells, ingurgitate 80 quarts in three minutes. Hence water, in the case of a siege, is more important than solid rations. With respect to the fasting men, the effects of starvation were less visible with those who imbibed water than with those who abstained. But death by inanition would arrive in due course, when corporeal energy succumbed. The explanation is facile; the liquid losses in the system take place in several manners; the diminution of the liquid part of the blood, in the case of inanition, renders the blood thick and viscous, thus blocking circulation, and so arresting the processes of nutrition. Though a horse cannot go beyond 25 days subsisting solely on water, or beyond five when kept exclusively on dry food, yet these periods may fluctuate following the animal's age, condition and movements.

HOLLOW POROUS EARTHENWARE used in the Chicago Auditorium ceiling was thoroughly although accidentally tested recently. A coping stone, weighing nearly two tons, fell from the outer wall of the Auditorium building, cut its way as with a chisel through the tiling of the first intervening floor, and stopped on the next, where it was allowed to remain on exhibition for several days to show the strength of the material. When the hole was patched up, the floor was as good and strong as new, not having been disturbed in any other part.

NATURAL GAS.—One of the disadvantages of natural gas, remarks a contemporary, is the fact that for various reasons it often gives out during the night, and, however short its temporary absence may be, all the fires go out. To prevent the gas from filling the house on its return, "safety valves" were invented, which at once close the pipes. Now a young man of Pittsburg has invented an electric apparatus for waking up one to light the fires at the proper time, and whether or not it will become popular, it is certainly ingenious.

WEIGHT OF DIFFERENT COALS. — Walter Johnson, in his report, printed in 1844, on American coals, after investigations under the direction of the United States Government, found that the average weight of anthracite in lumps was 53 05 pounds per cubic foot. He found for Beaver Meadow coals, 54 9, 56 3, and 55.1 pounds; for Schuylkill coal, Forest Improvement Company, 53.6 and 53 8; for Lehigh Company's coal, 55 3; for Lackawanna coals, 48.9; and for Lykens coal, 48.6 pounds.

LONG-DISTANCE TRANSPORTATION.—A party of Denver men are engaged in a project that contemplates the transportation of natural gas from the wells in Pennsylvania to Denver by rail. The cars are made of steel boiler plate, and much in the form of oil-tank cars, and are expected to contain from 10,000 to 15,000 pounds of gas when compressed. It is to be used as fuel to operate the engines of a cable line of street cars.

A STOVE PIPE RIVETING MACHINE.—A recent invention is a machine for riveting stovepipe. In the old way each of the six or nine rivets in a piece of pipe was drawn and driven separately. By the use of this riveting machine all the rivets are drawn by one drop of the hammer and all of them are set by one drop of the hammer. One man with this machine can turn out from 600 to 1000 joints of pipe per day.

TO LAY OFF A RIGHT ANGLE.—If you wish to lay off a right angle of some size, make a skeleton triangle of three strips of wood, having a length respectively of three, four and five feet, securing the corners firmly. The five-foot strip will form the hypothenuse of the triangle and the other two strips will form the two sides of the right angle. It is handy for excavations, embankments, and masonry.

AN OUT-OF-WORK FUND.—Several New York unions have established "out-of-work" funds, and some unions in other cities are following their example.

ENGINEERING NOTES.

NEW FEATS OF ENGINEERING SKILL IN RUSSIA.—Many of the great works executed in our days in Russia, and many others which only a future generation will carry out, were conceived in the days of Peter the Great. One of the most interesting of these is the grandiose scheme for connecting the Baltic with the White sea by means of a canal. This project would seem now, in parliamentary parlance, to have come within the "sphere of practical politics." The motives of the Government are manifold; not only strategical, but economical—for they are sincerely desirous of doing something for an immense rich territory suffering from the absence of roads and water-ways. Not only have experienced engineers been sent out to survey the country and report on the difficulties and the cost of construction, but they have already finished their work and handed in their report. They assert that the difficulties are practically *nil*, and the project quite feasible, and they estimate the cost of the canal, which will be 210 Russian versts long, at 10,000,000 roubles. The matter was discussed by experts under the presidency of Gen. Ignatief, and only one voice was raised in opposition, and that not on technical grounds. The dissentient was actuated by a strong desire to see the ten millions expended in works which he considered more urgent in his part of the North country. Miliutin and Gen. Ignatief expressed themselves very strongly in favor of the project, which will probably soon be realized.

THE CANTILEVER BRIDGE is an American invention, although it has been developed by Messrs. Fowler and Baker, British engineers, in their huge bridge now building across the Forth, in Scotland, of size which dwarfs everything hitherto done in this country, not excepting the Brooklyn bridge. The system is devised to dispense with staging or false works, when from the great depth or the swift current of the river this would be difficult, or, as in the case of the Niagara river, impossible to make. The first design of record was that of a bridge planned by Thomas Pope, a New York ship-carpenter, who published a book in 1810, giving his designs for an arched bridge of timber, with a span of 2400 feet, across the North river at Castle Point. The first railway cantilever bridge in the world was built (commenced in 1854) over the deep gorge of the Kentucky river, being 300 feet high with a center span of 330 feet.

NEW DEVICE FOR UTILIZING WATER-POWER. A Russian engineer, M. Tayn, has invented a new means of utilizing a current of water. The apparatus consists of an endless cable, carrying a series of canvas cones which open and shut like an umbrella. The endless cable passes over a double drum on board a pontoon, and at the other end over a pulley suspended from a buoy. The current opening the cones on the rope moves the cable at a certain speed, and this drives a shaft or drum. On the upper part of the rope the cones are naturally closed by the current to which they present their points. This plan, it is suggested, would serve to raise a certain quantity of water for the purpose of irrigation.

THE MOST ECONOMICAL MEANS OF TRANSPORT.—M. Demoulin has calculated that a cargo boat driven by a triple-expansion engine is by far the most economical of all means of transport. It carries 2500 tons of coals and goods, consumes 10½ tons of coal in 24 hours and easily makes 8½ knots an hour. Thus, 11 grammes, or not one-half ounce of coal, is sufficient to develop the power necessary to carry a ton at the rate of 4½ meters or 14 feet per second. Another calculator has calculated that a half sheet of note paper will give when burnt enough heat to carry a ton a mile in an Atlantic ship.

TONNAGE OF STEAMERS.—The tonnage of some of the largest steamers traveling the Atlantic is as follows: City of New York, about 9000 tons, of the Inman line; City of Rome, 8415; Furnessia, 5495; Belgravia, 5000, of the Anchor line; Alaska, 5500; Arizona, 5300; and Montana, 4320, of the Guion line; Aurania, 4030; Servia, 3971; Pavonia and Cephalonia, 3490; Umbria, 3401, of the Cunard line; the Amerique of 3034, and the France of 3033.

A CURIOUS CASE of the settlement of the piers of a bridge is reported from Knin, in Austria, where the abutments of the Oraznica bridge have sunk a depth of 20 feet in the river-bed since 1886. As the settlement progressed, the masonry of the bridge was built up correspondingly so as to maintain the same road level. The settlement has now entirely ceased and no further trouble is apprehended.

THE CAPE COD CANAL.—They are still pegging away at the Cape Cod ship canal, which was begun nine years ago. The contract requires the work to be finished by June 20, 1891, but as there are seven miles yet to be dug, and as during 1888 there was only about seven-eighths of a mile opened, the prospects are not good for the fulfillment of the contract.

A RUSSIAN CANAL CONCESSION.—The Government has granted a concession for 81 years to a company to join the Black sea and the Sea of Azov.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Amador *Ledger*, Feb. 23: Drifting at the North Star continues, but there are no new developments to chronicle. If no change occurs soon, it is probable that sinking will be resumed, and the shaft deepened to the extent of 200 or 300 feet, before any further drifting will be done. If nothing is discovered at that depth, the company will most likely throw up the property.

POCKET.—Another rich pocket was struck in the Reed & Askey mine, near Clinton, last week. This property is proving a genuine bonanza to its fortunate owners. The general character of the rock pays well, yielding $6 or $7 a ton, while these pockets, which are so frequently met, bring up the average to probably the highest figures reached by any mine in the county. The mill is kept running steadily. We hear that the owners have been offered $30,000 for the property, which was refused. They say they have more than that in sight. Connection was made last Saturday at the Alpi mine between the shaft, 50 feet deep, and the tunnel which has been driven in from the gulch a distance of between 70 and 80 feet. The character of the rock looks very encouraging. Samples which have been left at this office ought to yield, according to the opinion of expert miners, between $10 and $20 per ton. But very little work will be done at the mine from this time on until a mill is erected. The Volcano Gold Gravel Co. at Volcano have only sufficient water to enable them to run an hour or two each week. They are said to be in excellent pay gravel.

ALICE.—*Dispatch*, Feb. 23: Work at this mine is being pushed right along. A recent cleanup gave a profit of about $2.50 per ton, after deducting working expenses. This valuable property is owned by Messrs. Petre, Tripp and Littlefield, and is located a short distance above Big Bar bridge, on the Mokelumne river. Their new mill works like a charm. Mr. Nooner is still at work sluicing off the surface ground with the expectation of unearthing a rich quartz vein. He has been working this claim, which is about a mile and a half southeast of Butte mountain, for two or three years and during that time has cleaned up $6000. The gold is all found in decomposed quartz, thus giving the impression that it must be detached from a body of rich quartz. The Mello brothers are working their gravel claim back of Butte mountain.

Fresno.

FINE GOLD DISTRICT.—Cor. Fresno *Expositor*, Feb. 23: The Zebra, located in Fine Gold district, was recently purchased by Messrs. Farrington & Rogers of San Jose. There is an immense body of ore in this mine. Three tunnels have been run on the ledge 300 or 400 feet in length each, and about 80 feet apart. There has been little or no stoping done as yet. The tunnels have been connected by chutes, and everything is in readiness for the extraction of unlimited quantities of rich ore. An incline shaft is being sunk in the face of the lower tunnel to supply water to run the mill, which will be built at the mine if a sufficient quantity of water can be found. The Wilson mine is still working and looking well. Negotiations for the purchase of this property were going on some time ago, but for some reason the sale was not consummated.

HILDRETH.—Fresno *Expositor*, Feb. 23: T. W. Robinson of Hildreth reports the Abbey mine looking up. Eight or ten extra men were put on it Friday. There are a great many prospectors in the hills. On this side of the San Joaquin river, at Temperance Flat, sufficient men to work the mines cannot be procured. At the Jackson mine this drawback greatly interferes with the developing of the mine. Many rich claims have been struck at Temperance Flat. Near Auberry, W. L. L. Witt & Co. have been developing a promising claim, and at the depth of 30 feet have been rewarded by striking a three-foot vein of rich gold-bearing quartz. This late find has greatly encouraged the miners and prospectors of that section, and the hills are eagerly traversed by prospectors.

A BIG STRIKE.—During the past few months many rich developments have been made in the Hildreth and Toll House mining districts, Fresno county. This afternoon a courier from the Hildreth district brought news that a rich strike had been made in the Crown Point and Belcher mines, near Hildreth. This mine is owned by Baldenabro & Ball. The strike exceeds all expectations of the owners of the mine. The ore works $80 per ton over and above the cost of getting out and working it. The ledge in sight is six feet wide and 300 feet long. A five-stamp mill is running night and day crushing the rock.

Mariposa.

SHERLOCKS. — Mariposa *Gazette*, Feb. 23: Reports from Sherlocks show that two feet of snow was the depth of the fall on the hills out there. With that much snow, the miners of that locality ought to be able to save a little water for washing up. Mr Lorenzo Alvord finished his contract at the Alabama mine on Whitsocks on the 10th inst., after sinking the shaft to the depth of 62½ feet. He has done his work in first-class order, and the mine is now in good condition to show experts.

Monterey.

LOS BURROS.—Monterey *Democrat*, Feb. 23: Jas. Goodrich is in town from the Los Burros gold mines. Mr. Goodrich is an old miner and has faith in the Burros. He has a claim himself and it pays him all the time. He has a tunnel in 120 feet and an incline 30 or 40 feet and his claim grows richer as he develops it. Close to him John Bushnell has a claim from which he is taking out good-looking quartz and free gold all the way along. Close to Mr. Goodrich are also at work on good claims three Danes, Messrs. Malm, Soberg & Olsen, and that old veteran of the mountains, "Rocky," and Joe Logwood are also at work upon a claim near by that looks well and is no doubt rich in the precious metal. Mr. Goodrich says that preceding the storm of last Thursday, it was very cold in the Burros, and that when he left, the ground was covered on the north side of the mountain two feet deep with snow.

Napa.

IN CALISTOGA DISTRICT.—*Calistogian*, Feb. 23: Work continues as usual in the Palisade mine, and the reduction-works are running regularly. There is plenty of ore, and will be for several years to come. Very little prospecting is being done in the district, however, despite the fact that the Palisade property is satisfactory every way and very valuable. Many believed that when the reduction-works were running and producing bullion the fact would stimulate men to action and the result would be a greater amount of prospecting and finding of more veins. But such has not been true, and the fact is somewhat disappointing. If the opening of a good mine and production of a satisfactory amount of bullion will not create interest in mining business here, we do not know what will. Perhaps if one or two more mines and mills were in operation, men of means would pay more attention to the district. That other mines will be opened here we do not doubt, but a great deal of time seems necessary for the work.

Nevada.

IMPROVEMENTS AT THE MINES.—*Tidings*, Feb. 21: Work on the new hoisting plant for the North Star mine was instituted to-day by the Risdon Iron Works, through Mr. Cutter, a sub-contractor. We have heretofore made mention of the improvement as projected. When it is completed the North Star will be thoroughly equipped for sinking the shaft to a depth of 3500 feet, double the depth attained to date. And yet this mine was abandoned years ago as worked out. The new mill at the Pittsburg mine was started up for the first time yesterday and run for a few hours. Everything worked satisfactorily, but of course there are a few minor matters to be attended to, and in consequence the mill will not start up regularly until to-morrow, or perhaps Saturday. This mill is of 10 stamps and the accessory machinery comprises the latest approved gold-saving apparatus. The building has been so constructed and the machinery so arranged as to enable automatism to a large extent, thus conserving economical reduction of the ore. Supt. Elliott believes it to be the finest and most complete structure of its kind on the Pacific Coast, or in the world. Several hundred tons of ore are on the dump in readiness for reduction, and such is its quality that the superintendent confidently believes that the first month's run of the mill will yield sufficient to pay for that improvement. In a week or two the 1100-foot levels will be started, over 100 feet in depth having been attained in the shaft since the mine passed into the hands of the present manipulators. The ledge in the shaft varies in size from a foot to seven feet, and the character of the ore is such as to convince the management that the Pittsburg is a first-class piece of property. This mine, too, has had many reverses, has been shut down several times, etc., and its ore has been libeled as not worth a dollar a ton on an average. Verily, it is true that after 35 years of quartz mining in this county, our miners are just beginning to realize that the industry is yet in its infancy—that not half of the secrets of the earth in this relation has been ascertained.

THE DELHI.—*Herald*, Feb. 21: Good news continues to come from the Delhi mine. A new shoot of very rich ore has been discovered south of the one heretofore worked. An intermediate tunnel between No. 1 and No. 5 was run south and tapped this new formation. After leaving the old shoot the ledge narrowed down to a mere seam for a distance of 80 feet, where it came to a width of 4 feet. On this ledge the tunnel has been extended 200 feet, and how much longer the shoot is of course is not known. It is a fine body of ore all the distance opened. Some of it is very rich in free gold, beautifully imbedded in the quartz and surrounded by sulphurets and galena. The rock is of an entirely different character from that hitherto worked. At this point there are 400 feet of backs. Tunnel No. 3 has been extended 1100 feet, 500 feet of which was through country rock. There is a fine body of ore in the face of this tunnel. In the upraise there is a 3-foot ledge, which assays $87.50 in free gold, besides rich sulphurets. A river tunnel will give 400 feet backs under tunnel No. 3. The trend of the Delhi is north and south and it pitches nearly vertical. The country rock of the hanging-wall runs parallel with the ledge, but the footwall runs up against the ledge obliquely and carries feeders of quartz in the seams. The walls are from 8 to 9 feet apart, the hanging being very hard. The quartz also is hard to break. The mill is run by water-power. The rock is raised in cars from the mouths of the different tunnels to the rock-breaker, from which it falls into an ore bin and from thence to the batteries. There are eight concentrators in use, four Frues and four Triumphs. The bullion output of the Delhi has been large, but bids fair to keep up its record for many years. It is under the able supervision of Chris Mallon.

Placer.

QUARTZ AND GRAVEL NOTES.—Placer *Herald*, Feb. 23: The White boys have taken out several thousand dollars from their ledge on Duncan Hill. Henry Purdy is running a tunnel for copper at Whisky Diggings with good prospects of striking it rich. Ned Gilbert reports scarcity of water at Oregon Bar. The miners can work a few hours only each week. The Hidden Treasure mine still rolls out its wealth of gold. The dividend to each shareholder was $115 for January. George Geissendorfer informs the *Herald* that he is running a tunnel on the Live Oak quartz mine, near New England mills. Thomas Sheridan has run a powder drift in the Pride of the Divide mine, and is hoping water will come soon to help him make a cleanup. "Thirty days" should have been "13 days" in the notice given the cleanup at the Mayflower mine in our last week's issue. The mine has yielded over $70,000 since the mill started on the 11th of December last.

Shasta.

DISCOVERIES.—Shasta *Courier*, Feb. 23: Two rich gold-bearing quartz ledges have recently been discovered near town, and are being worked with favorable prospects. One by Joseph Bucher near the residence of D. Lynch on Nob Hill, and less than a mile from this office; the other by the Schroter brothers just north of town.

FROM LOWER SPRINGS.—Our miners here are a little slack in proving up their mining property. Some who pretend to have the best ore are very careful to let it remain as nature placed it. As for myself, I am very much delighted over good prospects, no matter who has them. We find that the miners are not the only ones that take part in our mining industry. It is Illinois capital that is with us in our struggle, and have placed an expensive plant at the Four Mile House, with the intent of working all ores, no matter how rebellious they may be. It is well known that Capt. Atkins has spent the best part of the last two years in assaying and examining the ores in this district. With his careful assaying and ability, have come to the conclusion that the works will, when started, be a complete success, and we should congratulate the captain on his untiring effort in accomplishing his desire, and now is the time for miners to bring forth their hidden wealth. The cry "no mills" has been for a long time. Now pitch in, miners, and show up, for there is a boom coming.

Sierra.

PORT WINE.—*Mountain Messenger*, Feb. 23: Riffle Co. is taking out good gravel and has a crowd at work. They will get their claim opened up in good shape by spring. The Union Con. M. Co. are also taking out big pay gravel, from $4 25 to $4.62 to the carload, and putting on all the help they can work. James Jones and T. Edwards are still drifting under town in their old diggings.

WIDE AWAKE.—J. O. Jones of Forest City has been appointed superintendent of the Wide Awake drift mine, Alabama Hill, and took charge of the property last week.

OXFORD.—The Oxford quartz company is now working three shifts, two running north and one south.

TUNNEL.—Tom Bessler is again at work running his tunnel for quartz in the ravine above the Catholic church.

QUARTZ.—Jack Hughes is working the regular force of men on the Montpelier quartz claim.

THE NORTHERN BELLE. — *Tribune*, Feb. 22: This mine is situated about one-half of a mile back of the Marguerite mine at Loganville, and is owned by Swan & Co. The owners are confident that it will prove to be a most profitable mine. Two tunnels have been run at the mine. Tunnel No. 2 is in a distance of about 60 feet. A ledge of five feet, showing much free gold, can be found there. No. 1 tunnel is in but a short distance and shows up a well-defined ledge of about three feet. At present the company is engaged in erecting four stamps of the old Keystone mill on the Northern Belle, and it will not be very long before they will know just what kind of a mine they have. The mill will be run by water-power.

THE CAL. CON. M. CO.—Pushing work ahead at a rapid rate. The owners have great expectations as to the outcome of the mine. The ledge that they have is a good one and prospects well.

Trinity.

NEW RIVER.—*Western Watchman*, Feb. 23: Mr. G. C. Sarvis got in from Battle creek in the New River section last Saturday. He says everybody is at work; it is a very busy camp and has bright prospects before it. During his stay he has been at work opening up two claims which he owns, the Occident and Goodenough. On the former he exposed a good body of about $20 ore, while on the latter he struck free gold and sulphurets. Gus Gutzen, who owns an extension claim on the same ledge, called the Golden Gate, has developed a 16-inch vein bearing $30 rock. The Ridgeway, 600 feet distant on line with same ledge, is in the hands of an English company, and they are working 15 men getting out necessary timber and tunneling. They are running a tunnel which is to be 700 feet long and will tap the ledge at a depth of 400 feet. It is the plan of the company to spend $25,000 in the development of the mine. J. S. Thomson is operating the Excelsior mine with a quartz-mill and doing well. The Mountain Boomer, owned by Clements & Ladd, is being worked right along with good pay. The mine has been bonded for $60,000. The extension of the Ridgeway, called the Hard Tack, run through 15 tons of rock and cleaned up $185 per ton. The weather has been unusually open. About January 10th there was a heavy fall of snow which went off gradually and is now nearly all gone. Water is scarce; there is not as much power for the quartz-mills as is required, and the placer mines are having a hard time.

A GOOD PROSPECT.—Trinity *Journal*, Feb. 23: Ed Jose tells us that there is a chance for a bonanza in Trinity Center. Last summer a prospector found good quartz on Snow creek, just above the town. He returned several days ago accompanied by Mr. Roberts, a well-known San Francisco mining man. They have contracted for a tunnel to be run in on the find 100 feet. Ed says a specimen shown him was the finest he ever saw. The piece of quartz was about 3 by 2½ inches and was studded thick with gold, and presented a beautiful appearance, as the quartz was white.

Yuba.

BLUE POINT MINE.—Grass Valley *Tidings*, Feb. 21: Patrick Campbell has renewed a lease with Marysville men to work the Blue Point gravel mine, at Smartsville, for two years from the first of the present month. At the present time, with an arastra and a force of 20 men, the mine is yielding at the rate of $4000 per month. Next week it is the intention to put in another arastra, and hoisting works and a rock-crusher are to be added. The working force is to be increased to 40 men, and with these improved facilities it is expected that the monthly yield of the mine will be increased to $10,000.

Tuolumne.

TIOGA.— Union *Democrat*, Feb. 23: Contracts have been let to parties in Groveland to haul a large amount of freight into Tioga the coming summer. This looks favorable for the opening of some of the mines in that district. These mines, which are situated in Tuolumne county near the Mono line, have long been known to be very rich, having plenty of water and other facilities for working them, the only drawback being the severity of the climate, which only allows surface mining to be done for about six or seven months in the year. The leads in this district are numerous, the Sheepherder vein being the principal one. This is 30 feet wide in places and is very rich both in silver and gold. Many other leads in the neighborhood are also rich; assays showing the rock in some of them to average $900 a ton. These mines are destined at no distant date to be extensively worked. The Great Sierra Mining Co. has large interests there, and the contracts lately let by them may be the commencement of operations upon their property. Those who are fortunate enough to have locations in the Tioga or Mt. Gibbs district, which is near Tioga, should by all means hold on to them, as they will no doubt soon be valuable property.

BONANZA.—Tuolumne *Independent*, Feb. 23: Another rich strike was made in the Bonanza mine on Saturday last, and on Wednesday of this week this second pocket was cleaned up, yielding about $20,000. This makes about $85,000. It is hoped another pocket may be uncovered very soon, as they will commence sinking on the vein. Most of the gold in this last find was taken out in two big chunks, and before they were broken up, on Tuesday afternoon, crowds of men, women and children flocked to the mine to see them.

NEVADA.

Washoe District.

HALE AND NORCROSS. — Virginia *Enterprise*, Feb. 23: On the 400 level No. 1 west crosscut is now advanced 90 feet. From the joint west drift on the north boundary have started a drift south, following a stratum of good ore. On the 500 level have resumed work in the south drift, which is now advanced 119 feet. The upraise and stopes above this level continue to yield ore of good quality. The 500 and 700 levels are supplying the usual quantity and quality of ore. The north upraise on the 700 level is now advanced 60 feet in low-grade quartz, showing spots of good ore. On the 1300 level the north drift is now advanced 85 feet. This drift shows spots and bunches of good ore. Have hoisted during the week 1054 tons of ore; have shipped to the Mexican mill 1081 tons, and milled 1035 tons. Average battery samples assay $21.78 per ton. Have bullion on hand and previously shipped for the month amounting to $37,041.70.

SAVAGE. — On the 400 level have commenced stoping ore in the north drift from the west crosscut on the south boundary. The ore is of good grade. No. 2 southwest crosscut has been advanced 42 feet. This drift passed through two feet of fair-grade ore. Have turned a drift south, following this ore. From the north and south drifts on this level are extracting ore from the old stopes. On the 500 level have started west crosscut No. 3, our south boundary. This drift is advanced 29 feet. Are extracting ore from the old stopes on this level, also from No. 3 east crosscut on the 600 level. Have hoisted during the week 587 tons of ore, have shipped to the Rock Point mill 428 tons, and milled 478 tons. Average battery assays, $21 per ton. Have bullion on hand and previously shipped for this month amounting to $16,837.

BELCHER.—The 200 north drift is out 490 feet, having advanced 31 feet during the week. Will soon connect with the Crown Point 160 drift, assoundings between the two show them to be close. Have started the winze below the 1100 joint drift and are down 22 feet, leaving about 23 feet to sink and connect with the 1300 raise. Are timbering the 1100 north drift at the point of connection.

CROWN POINT.—Have stopped No. 2 east crosscut at a distance of 97 feet in, and started a west crosscut (No. 1) opposite it, which is now out 16 feet in a mixture of quartz and porphyry. Also started a north drift on the 600 level, at the top of the 700 raise, to find the upward continuation of the ore found in the raise.

JUSTICE.—Have advanced the 400 level north drift 39 feet during the week, making its total length 946 feet. Advanced the 370 level drift 23 feet; total length, 173 feet. Shipped to the mill 200 tons of ore, the battery samples of which averaged $23 a ton. Shipped during the week $2925 worth of bullion.

CON. IMPERIAL.—East crosscut No. 2 on the 1100 (Yellow Jacket) level is now in 83 feet, 12 feet having been made during the week. The face shows quartz and porphyry. Repairs to the main north lateral drift are still going on.

CHALLENGE CON.—The usual work has been done in the mine without any important developments. Ore shipments to the Brunswick mill amounted to 130 tons, averaging, by assay, $26.41 per ton.

OVERMAN.—The upraise from the east drift has been extended about 20 feet; total distance, 51 feet above 226 level. The formation is porphyry and quartz.

SEG. BELCHER.—Have started the winze below the 1100 level drift and are down 22 feet, leaving about 23 feet to sink to connect with the 1300 raise.

CHOLLAR.—The usual work of exploration is progressing, and the usual quantity of ore is extracted and reduced at the Nevada mill.

BALTIMORE.—Hoisting ore from the 338 level, from the ledge in its most western workings, and saving the same for reduction.

ALTA.—The ore reserves from the 800 to the 1100 level are yielding their usual quantity of ore, which is being reduced at the mill.

CONFIDENCE.—The usual quantity of ore is now being sent to the Brunswick mill. The average assay is $26.41 per ton.

YELLOW JACKET.—Have stripped no ore this month, but are prospecting the upper levels of the mine, as usual.

SCORPION.—Progress is only represented in the crosscut on the 300 level.

ANDES.—The work of reopening the 175 level is progressing favorably.

NEW YORK.—Still drifting north on the 800 level in vein material.

BULLION.—The usual work of exploration only is reported.

Bernice District.

THE MINES.—*Silver State*, Feb. 23: News has reached here that W. W. Williams is preparing to resume operations on his mines at Bernice, and will set a number of men at work about March 1st. Something of a boom in the mines of that district and Cottonwood is looked for the coming summer.

Columbus District.

CANDELARIA.—Inyo *Register*, Feb. 23: Candelaria is at present extremely quiet. About 20 men are working at the Mt. Diablo, the ore from which is taken to Soda Springs for working. A small force is at work in the Georgene, and some digging is being done on smaller claims. The Columbus, Metallic, Princess, Holmes, and other mines which have heretofore poured their bullion into the world's coffers, are at present closed. Supt. Wescott, Secretary Judson, and day and night watchmen remain to take

care of the interests of the Candelaria Water & Milling Co. The company's fine mill is lying idle, as is all other machinery in the vicinity except at the Diablo hoisting-works. The impression created by a visit to the camp and a cursory inspection of mines and mills, is that there is an abundance of life yet in the old camp, and it is only lying dormant awaiting something—probably the rise in silver—to be again a good town. The settlement of impending lawsuits will remove the bar to work upon some of the largest mines, while a jump in the silver market to 100, 105 or 110 would put an end to the present stagnation, in that vicinity as well as many others. The boom at Candelaria, for which all wait in patience, would mean better things for Belleville. That once lively center is now a mere shadow of its former self. The two 20-stamp mills are lonely, rusting monuments of the busier past, while dozens of vacant houses make the contrast between present and past only the stronger. Not over 15 or 20 people remain there.

ARIZONA.

MOHAVE MINES.—*Miner*, Feb. 23 There came in from the Lone Star, Mineral Park, about seven tons of ore, on Wednesday. This ore is high grade, and the owners expect a handsome sum from it. The sampling works have not been running steadily this week, owing to a scarcity of ore occasioned by last week's storms. Dan Maloney came down Sunday from the Broncho mine, Wallapai mountain. Dan has a shipment of very rich ore awaiting transportation, which is delayed by the late snow. Supt. Mackenzie is working 18 men on the Prince George. At the combination shaft they have ore both north and south, and have about 400 sacks on the dump, which will be brought in as soon as possible, as the roads are not in the best condition since the storm. The main ore body seems to be in the Prince George North, while heretofore the rich ore has come from the Prince George South. The Tintic gold mine at Chloride has proven even more promising and permanent than the owners anticipated when they resumed work some three weeks ago. From reliable information received from the mine we learn that they are now down 94 feet, and while they thought they had all the ledge at 74 feet, they discovered an additional two feet in sinking, which now gives them six feet of free-milling ore. By way of testing the vein they worked two tons in an arastra last week from which they got a little more than one pound of gold bullion. There is considerable water in the mine.

HEAD CENTER MINE.—Tombstone *Epitaph*, Feb. 23: Quite a stir has existed in mining circles for a day or two past on account of the relocation of the Head Center and Yellow Jacket mines on the hill and lying between the Contention mine on the south and the Tranquillity mine on the north. As there were conflicting rumors in the air as to the condition of the title to this property, we have taken some pains to get at the facts and find them to be about as follows: Application was made by the Head Center Co. for a patent to those mines as far back as 1882 or 1883. A survey was made, notices posted on the claim and publication had, but for some unaccountable reason all proceedings were stopped at this point, and no entry was ever made. The company, apparently, acting on the belief that an entry had been made and the purchase price paid, which, under the decisions of the courts would have been equivalent to a patent, have neglected from year to year to perform any assessment work. The fact that no entry had been made becoming known to Mr. Perasich, he relocated the claim, with a fair prospect of holding it, and is now posing as a prospective bonanza king.

BRITISH COLUMBIA.

GOOD ORE.—Donald *Truth*, Feb. 23: The Warm Springs district on Kootenay lake is a coming mining camp. Of its quartz mines, G. B. Wright's Number One is the richest yet developed. Its ore will average over $300 to the ton. The Great Falls Smelting Co. has made an offer to buy 50,000 tons of the ore at a price up in the hundreds. At present there are 17 men at work in the tunnel, which will have to run in about 300 feet. They are working 8-hour shifts, and are now in 140 feet. Two shifts are taking out ore in the incline when not engaged in surface preliminary work; but when the tunnel strikes the ledge Mr. Wright expects to make things hum. The mine is located 3½ miles from the warm springs on the lake's shore, and the snow is about four feet deep at it. A. D. Wheeler has six men at work on the Lei-Her-Go-Gallagher claim, and two on the Krao. Both claims are rich and opening up well. The Little Donald is another first-class claim, on which seven men are at work taking out ore. Across the lake Dr. Hendryx has several claims, one of which, the Blue Belle, is developed into a mine. After running a tunnel, six men are now at work crosscutting the ledge to find its width. They are in 63 feet, "and God only knows how much wider it is." The ore is low grade, but as the mine is right at the water's edge, it is bound to be a great property.

MONTANA.

WEST OF ANACONDA.—*Review*, Feb. 21: In regard to the prospects west of Anaconda, and especially in Oleson gulch, a correspondent sends the following: The Blue-Eyed Nellie, situated on the divide between Oleson gulch and Foster creek, and adjoining the Antelope, the shaft is down now about 75 feet and they have a pay streak of carbonates 15 inches in width which runs high in silver and lead. The owners of the Antelope are now shipping ore of a very high grade. They have a nice lot of ore in sight at the 100-foot level. Adjoining the Antelope is the Monitor lode, owned by Layelle, Strong & Co. This mine is worked by a tunnel which is in 145 feet. They have cut two stringers of ore in the last 15 feet which is a good grade of carbonates, and the owners feel confident that when the main lead is reached they will have a good paying property. They expect to strike the main lead within the next 25 feet. The Fairfield is the next adjoining claim, owned by Fairfield and others of Butte. They are down something over 100 feet, which has been mostly iron and talc. It is their intention, we understand, to sink another hundred feet before running any levels. The Morgan Evans is the next claim. It is owned by Thomas & Co. of Butte. They have a nice lot of ore on the dump, and I understand they commence shipping next week. The Little Pittsburg, owned by Jos. Corbin & Co. of Anaconda, is the next adjoining claim. They have a shaft down 75 feet, in iron carbonates, but have stopped work until spring, when they will put up a whim and resume work. We have just learned that Mrs. Rae & Miller have stocked the Antelope mine for $150,000 and will largely increase the output of that mine. The Cable mill has resumed operations, and will, we learn, make a long run.

NOTES.—Montana *Mining Review*, Feb. 23: Several of the mines in the neighborhood of Radersburg are shipping ore to Townsend, preparatory for treatment at the smelters. The output of the Granite mountain for the week ending February 13th was 39 bars of bullion, containing 64 274.24 ounces silver and 54.76 ounces gold. The coal company at Sand Coulee are erecting 15 new tenement-houses for the use of the increased force of miners they intend soon employing. Work will be resumed in a short time by the Indian Creek Mining Co. on their property, located at the head of St. Louis gulch. Eighty tons of ore were shipped to the Great Falls smelter last Monday from the Lexington and Bunker Hill mines, Rimini, and 80 tons more were shipped to-day. The third stack of the Great Falls smelter is being heated and will be in full operation by the first of next week. About 150 tons of ore per day is being received at the smelter. The Iron Mountain Mining Co. has uncovered a very wide body of ore, samples of which, as assayed by C. E. Kemp of this city, run from 75 ounces silver to 784 ounces per ton. A correspondent writing from Wickes, says: "Mining is looking well around this camp. It seems to be the uppermost question with a great many around here, because of the number of mining experts who visit us daily." Mining operations in the St. Louis district are lively for this season of the year, and the most satisfactory reports come from there. A new find is reported in the Buckeye, and ore is being shipped from the Gold Dust mine to the Great Falls smelter with very gratifying results.

IDAHO.

ORO FINO. — Idaho *Avalanche*, Feb. 23: The Leonard mill has been running steadily on ore from the Oro Fino mine for some time, and, as we write, is pounding away on good milling ore extracted from the levels of the Oro Fino mine, where, as we are credibly informed, there is an abundance of the same kind in sight. We hear that a cleanup will be made in a short time, when there is no doubt but that the fondest hopes of the owners will be realized.

SOUTH MOUNTAIN.—Mr. H. French thinks that before a great while South Mountain will again be booming, by reason of the numerous large lodes of galena in that district that will pay when the ore can be hauled to a near railroad.

JANUARY ORE SHIPMENTS.—Wood River *Times*, Feb. 23: The shipments of ore from Hailey during the month of January last amounted to 202,900 pounds, against only 43,500 pounds during the corresponding month of 1888—an increase of 159 400 pounds. This is a very gratifying showing.

NEW MEXICO.

DEVELOPMENT WORK.—Silver City *Enterprise*, Feb. 23: Two shifts are employed in the Four Hawks, Cooney district. The ore will be worked in the Sheridan mill. The Flagler smelting works have closed down, owing to the impassable condition of the roads. Martin Cox, manager of the Deep Down at Pinos Altos, reports that the mill runs about 10 hours per day. A tin assay was made this week by Hand & Beall on ore from Valencia county which averaged 10 per cent. Tin is a new metal in this section. A tramway will soon connect the upper ore body of the Sheridan mine with the Sheridan mill. As soon as a sufficient amount of ore can be taken out a run will be made, and if satisfactory, the mill will be supplied with ore from that part of the mine. A ten-inch streak of $1600 ore was recently encountered in the Maud S. at Cooney, owned by Capt. Cooney. The strike is in addition to the regular high-grade ore which has been coming from the mine. Work on the Snow Drift, Cow Springs district, recently purchased by Mr. Hussey, was commenced on Tuesday. The work is in charge of Paul Mitchell, a well-known miner of this section. Mr. Hussey is in receipt of plans and specifications for a new mill which he will soon erect. The erection of this mill will be a great benefit to that camp, as there is any quantity of low-grade ore there, as well as no small quantity of very high-grade.

UTAH.

SILVER REEF.—Salt Lake *Tribune*, Feb. 23: R. F. Gillespie, for the past five years superintendent of the Christy Mining Co., Silver Reef, has resigned and is now in the city on his way to Tacoma. Mr. D. M. Tyrrell, formerly superintendent of the Meadow Valley Co., Pioche, has assumed the superintendency of the Christy Co. The mill is running steadily and is crushing about 40 tons of ore per day, making the monthly product from $20,000 to $25,000 in silver. The company employs about the mill and mines some 90 men. The Stormont property is under lease to Robert Lund and T. P. Gillespie. The mill was started on the 10th for a few weeks' run on ore taken out by chloriders. It crushes about 20 tons per day, and will run as long as the supply holds out. In all, about 140 men are employed in mining in this silver sandstone district.

REVIEW.—Salt Lake *Tribune*, Feb. 21: The week has been a quiet one in mining circles, the storms hindering operations somewhat, though their effect will be good in the movement of ores as soon as the roads are fairly broken in the snow. The receipts in this city for the week were to the value of $134,793 in the aggregate, of which $81,467 was in ore, and $53,326 in bullion. For the previous week the receipts were $45,878.61 in bullion and $40,287.65 in ore, a total of $86,166.26. The Ontario product for the week was of bullion, 21,401.34 fine ounces; no ore sales on account of the bad roads making hauling impracticable. The Daly output for the week showed no transactions, the bad state of the roads preventing the hauling of ore. Fine bar receipts in this city for the week were to the value of $20,401; base bullion, $15,000; copper matte, $1200. Ore receipts in this city for the week were to the value of $17,261 by Wells, Fargo & Co. and $64,200 by McCornick & Co.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

From the official report of U. S. Patents in DEWEY & CO.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING FEB. 19, 1889.

397,976 —ROAD ENGINE—R. R. Doan, Sacramento, Cal.

398,247.—PLANE—H. Fry, Eugene City, Oregon.

397,920 —SHIRT WRISTBAND—W. E. Howell, Los Angeles, Cal.

397,986.—DRESS FORM—W. A. Johnson, S. F.

397,922.—HIP REIN SUPPORT—A. Kempkey, S. F.

398,054.—WINDMILL—F. B. Kendall, Olympia, W. T.

398,055.—PAVEMENT—J. E. Knoche, San Jose, Cal.

397,990.—DENTAL ENGINE—Ira G. Leek, S. F.

398,071.—POTATO PLANTER — J. E. Ohlson, Rockford, W. T.

398,081.—POOL REGISTER—Edward R. Robbins, Sacramento, Cal.

398 302.—SAW—W. T. Wilson, Marshfield, Ogn.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

DENTAL ENGINE.—Ira G. Leek, S. F. No. 397,990. Dated Feb. 19, 1889. This invention relates to the class of dental engines, and especially to the cranes or brackets by which the flexible power-conveyer and hand-piece are suspended from the wall, and may have imparted to them such variety of movement as will adapt the tire or bit carried on the hand-piece to work in any required position with facility. The object of the improvement is to provide for the proper variety of movement for the hand-piece which will admit of the use of the engine in all possible positions. By the interposition of power-transmitting rods in the tubular arm the inventor does away with all the cumbersome external belting which is used in connection with many dental-engine brackets for transmitting the power to the hand-piece chuck. In this machine the belting is only at the rear end and but a single pulley is used, in which respect the machine enjoys all the advantages of simplicity which are to be found in the common engines.

POOL REGISTER.—Edward R. Robbins, Sacramento, Cal. No. 398,081. Dated Feb. 19, 1889. This invention is a device for indicating or registering the points made in the game known as "fifteen-ball pool," and in connection therewith of an advertising device. It consists, first, of a case having horizontal channels with balls fixed permanently therein to one-half of their length, slides traveling in guides, so as to conceal or expose the balls, and an inclosed or uncovered chamber into which the slides run when the balls are exposed; secondly, of a registering device for ball pool, consisting of a case having channels, within half of which balls are fixed, slides traveling in guides over said channels, and having numbered disks fixed to them; and thirdly, of a case having a vertical central partition, horizontal channels extending across the case, and containing balls upon one side of the partition, in combination with covers sliding in grooves, and through the central partition, and having numbered disks or knobs upon them.

ROAD ENGINE.—R. R. Doan, Sacramento, assignor one-half to John H. Roberts. No. 397,976. Dated Feb. 19, 1889. This invention relates to improvements in that class of machines known as "road engines," and consists of a pair of engines mounted upon a frame and connected with a crank-shaft which is journaled upon said frame, a single bearing wheel so connected with the rigid crank-shaft as to be driven therefrom, while at the same time it may be turned from side to side in a horizontal plane for the purpose of steering the machine; and in connection therewith of a second crank-shaft journaled upon the frame parallel with the first one, and having a pair of driving wheels connected with it, the cranks of said shaft being connected with the first shaft by side rods, so as to be moved simultaneously therewith. This machine, which was recently illustrated in the PRESS, is especially adapted for rough mountain roads, where it has been doing good work for the past two seasons.

Legislative.

The Assembly bill providing for the erection and management of a State hospital for insane in Southern California, and appropriating $300,000 therefor, has been passed.

Senate concurrent resolution asking Congress to appropriate $2,000,000 to improve Sacramento and Feather rivers has been passed.

The members of the Manufacturers' Association have passed resolutions protesting against the passage of the Pinder bill by the Legislature. This bill provides that all wares manufactured in this State shall have printed or stamped on them a mark showing whether they were made by white or Chinese labor. The manufacturers at the meeting discussed the matter, and decided that they could not comply with the requirements of such a law if it were passed.

The anti-compact bill has been passed in the Senate by a vote of 37 to 1. This is aimed against the insurance compact.

The bill closing the sash and blind factory at the State prison has been passed.

A bill has been introduced entitled an Act to designate the quality of goods manufactured and prepared in the State of California, and to require manufacturers to stamp upon their products and manufactures the class of labor employed in their preparation.

National Iron Works.

On Sept. 9, 1888, the National Iron Works in this city were entirely destroyed by fire, sweeping away in a few hours the accumulations of years of patient toil and industry. But the proprietors, Messrs. Marshutz & Cantrell, with the indomitable pluck and energy of all old Californians, immediately set to work to rebuild, and now, after five months of incessant work, they see their efforts crowned with success. On the old site, at the northwest corner of Main and Howard streets, they have erected a massive brick building on a solid foundation of concrete. The lower story is 76 feet wide by 110 feet long, by 20 feet high. On this floor are placed all the iron-working tools necessary to carry on a general iron manufacturing business. On the northeast corner of this lower story is situated the large and commodious offices, 25x40 feet, which are plainly but substantially fitted up suitable for the business. Immediately back, and in the rear of the office, is the forging-shop, 45x60 feet, built of a substantial frame and covered with corrugated steel. This shop is fitted up with steam hammer, forges, cranes, etc., complete for all kinds of forgings. Immediately in the rear of the main building is situated the foundry, which is 75 feet wide by 137 feet deep and 30 feet high. This, like the forging-shop, is a heavy frame covered with corrugated steel and fitted up with the necessary cranes, core-oven, cupola, etc., complete for all kinds of iron castings. The second story of the main building is devoted to the drawing department and pattern works. This story is 18 feet high, 76 feet wide, and 110 feet long. On this floor are placed the necessary planers, band and crosscut saws and turning lathes used in the manufacture of patterns. These buildings have been built as nearly fire-proof as brick and iron can make them, and all the tools are of the latest improved design and from the best makers in the United States. Now with increased floor space and better facilities for handling all descriptions of work in their line, they will be pleased to see all their old customers and as many new ones as will favor them with a call.

Sheet Iron and Steel Pipe Works.

As a pioneer in this special branch of iron work on the Pacific Coast, Mr. Francis Smith takes the lead, having started the business in North San Juan, Nevada county, Cal., a little more than 25 years ago. Five years later Mr. Smith removed to San Francisco, where he established works on the site at present occupied, 130 Beale street, covering a ground space of 14,000 square feet. A commodious two-story brick structure shelters the heavy and improved modern machinery, steam-power, etc., which the requirements of a large and steadily growing business necessitate.

Some years since Messrs. Smith & Co. introduced American brands of sheet iron to the coast, taking the place of the inferior foreign article; and it has been pronounced by those using it as better in all respects. Sheet steel is also being used for pipes where lightness and greater tensile strength is a desideratum, and is giving such satisfaction as to warrant hearty commendations.

The firm manufacture pipe of all sizes up to five feet in diameter, and is adapted to all purposes, such as conveying water for power-wheels, hydraulic mining, town water-works, artesian wells, irrigation, electricity; smoke-stacks, air pipes, and other uses too numerous to mention. A patented rust-preventing composition of coal tar and asphaltum is applied to their pipe, making it more durable as well as keeping water pure where intended for drinking purposes.

They also make a specialty of coating pipes for the trade, for which there is a growing demand. In its regular course of business, this enterprising firm has contracted for and constructed the water works in many of the towns and cities of California and Nevada, and they now own and operate the water plants of Winnemucca, Nev., and Redding and Watsonville in California. Large experience in this branch of business makes their advice peculiarly valuable, and it is much sought by those contemplating works of the kind.

Messrs. Smith & Co. keep constantly employed from 40 to 60 men, mostly skilled hands, and it is justly due them to mention the fact that within the quarter of a century that has elapsed since the establishment of their business, there has never been a strike among their employes, nor a difficulty of any kind. Persistent application and straightforward business methods have advanced this firm from a comparatively small beginning to a business that extends over the entire region west of the Rocky mountains, as well as to Mexico, South America and Australia, being the largest works of the kind on the coast.

H. P. GREGORY & CO.

Cor. Fremont and Mission Sts., - - San Francisco, Cal.

IMPORTERS AND DEALERS IN ALL CLASSES OF

MACHINERY

SOLE AGENTS FOR

J. A. FAY & CO.'S WOODWORKING MACHINERY.

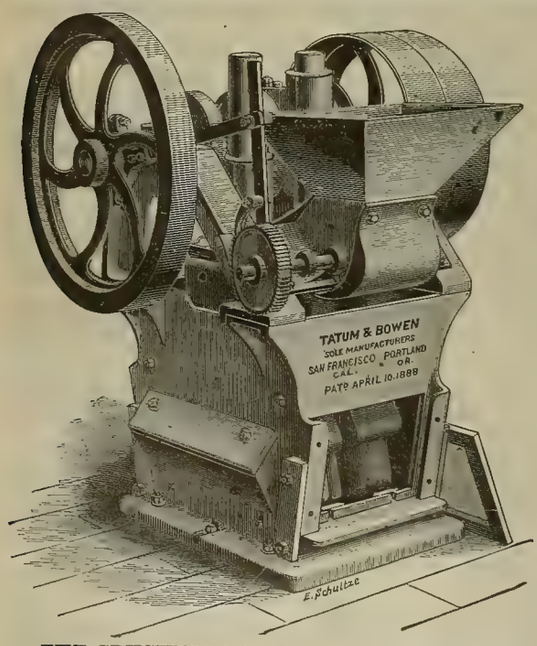
ENGINES and BOILERS

FROM 2 TO 100 H. P., ALWAYS IN STOCK

MILL SUPPLIES AND LUBRICATING OILS.



—THE—

PERFECTED DOUBLE Economic Quartz Mill.

Attached to each Mill is an effective

Automatic Ore Feeder.

THE CRUSHING is done by the rapid rocking movement in OPPOSITE DIRECTIONS of two heavy castings, the bottoms of which are slightly circular in form, and each provided with four shoes.

The Mill is a closer Gold-Saver and catches a larger percentage of the Clean-up in the Battery than any other Mill.

It costs less, in proportion to what it will do, than any other mill. There are no working parts to buy for it, no matter how long it is used, except shoes and dies. Capacity of Mill, 6 to 10 tons per day. Weight of Mill, complete, 6400 pounds.

We manufacture, to go with the Mill, an

IMPROVED ROCK BREAKER.

Power required for Mill and Rock Breaker, 6 H. P. SEND FOR CIRCULAR. Address:

TATUM & BOWEN,

34 and 36 FREMONT ST., SAN FRANCISCO, CAL.,

AND PORTLAND, OREGON.

MANUFACTURERS OF MINING AND SAW MILL MACHINERY.

E. E. EYRE, President. JAS. H. GRAHAM, Vice-Pres. & Manager. G. M. PINCKARD, Sec'y.

VULCAN IRON WORKS,

Successors to SAVAGE, SON & CO.,

135 to 145 Fremont Street, . - San Francisco, Cal.

MINING MACHINERY,

Stamp Batteries, Pans, Settlers, Etc. "Dodge" Rock Breakers, Pulverizers, Concentrators.

SAWMILL MACHINERY,

Refrigerating and Ice Machinery,

STEAM ENGINES,

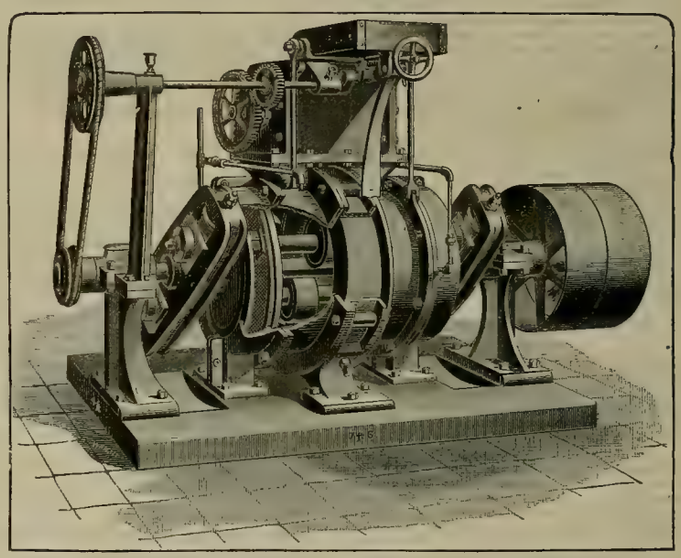
CORLISS, MYER'S CUT-OFF, PLAIN SIDE-VALVE.

Shafting, Pulleys, Hanger and Boxes, Etc.

Special machinery of all kinds. We have a large list of Standard Patterns, Gears, Pulleys, Boxes, etc. REPAIR WORK SOLICITED.

FRISBEE WET MILL.

This Mill, with a weight of less than 9000 pounds, has a capacity of three tons per hour of hard quartz to 40 mesh; is in successful operation and we guarantee its work as represented.



IT HAS NO MORE WEARING PARTS THAN CORNISH ROLLS,

And renewals will not cost over one-half as much as for stamps. Will run empty, or with small amount of ore without injury. The attention of parties having Cement Gravel is called to this Mill, as it will run 100 tons per day to No. 8 mesh; 30 to 35 H. P.

OUR DRY MILLS are the most economical ever built, and are extensively used with record of several years. No grinding in pans. Mill finishes to any fineness desired.

FRISBEE-LUCOP MILL COMPANY,

GIDEON FRISBEE, Manager, - - - 461 Howard St., San Francisco.

RAND ROCK DRILLS

AND AIR COMPRESSORS.

Of the Machine-Mined Mineral in the U. S., in 1887, three-quarters of the Iron Ore and two-thirds of the Copper Ore were mined with Rand Drills.

THE HIGHEST AMERICAN TUNNELING RECORD.

THE STANDARD

American Rock Drilling Machinery

For Mines, Tunnels, Quarries, Sewers, Grading, etc.

RAND DRILL CO.,

23 PARK PLACE, NEW YORK.

AMALGAMATING MACHINERY.

Stamp Mills for Wet or Dry Crushing. Huntington Centrifugal Quartz Mill. Drying Cylinders. Amalgamating Pans. Settlers, Agitators and Concentrators. Retorts. Bullion and Ingot Moulds. Conveyors. Elevators, Bruckners and Howell's Improved White's Roasting Furnaces, Etc.

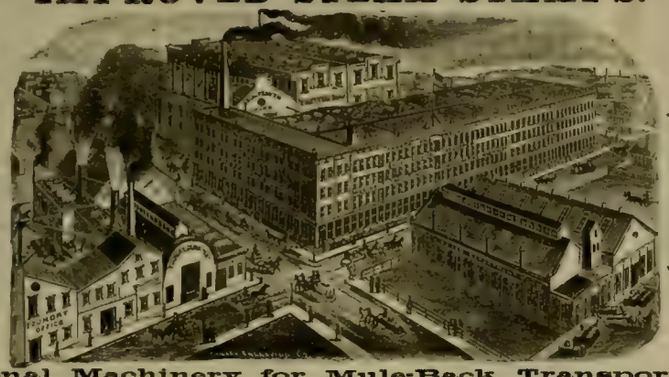
CONCENTRATING MACHINERY.

Blake, Dodge and Comet Crushers, Cornish Crushing and Finishing Rolls, Hartz Plunger and Collom Jigs. Frue Vanner & Embrey Concentrators, Evans', Calumet, Collom's and Rittenger's Slime Tables. Trommels, Wire Cloth and Punched Plates. Ore Sampler Grinders and Heberle Mills.

FRASER & CHALMERS,
MINING * MACHINERY,

Improved Corliss and Slide-Valve Steam Engines,
Boilers--Horizontal, Vertical and Sectional,
IMPROVED STEAM STAMPS.

Hoisting Engines, Safety Cages, Safety Hooks, Ore Cars, Water and Ore Buckets, Air Compressors, Rock Drills, Etc. General Mill and Mining Supplies, Etc.

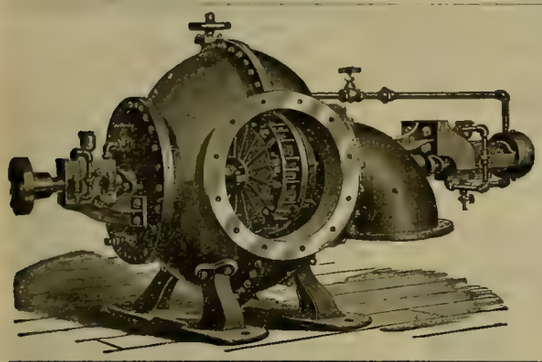


Pumping Engines and Cornish Pumping Machinery, Improved Water Jacket, Blast Furnaces for Galena and Copper Ores. Slag Cars and Pots, Roots & Baker Pressure Blowers, Suspended Tramways.

Sectional Machinery for Mule-Back Transportation.

General Offices and Works: FULTON & UNION STS., CHICAGO, ILL.

BRANCH OFFICES: NEW YORK, Room 43, No. 2 Wall St. DENVER, COLO., 1316 Eighteenth St. SALT LAKE CITY, UTAH, 7 Wes Second South St. LONDON, ENGLAND, 23 Bucklersbury, E. C. CHIHUAHUA CITY, MEXICO, No. 11 Calle de Juarez. LIMA, PERU, South America. JOHANNESBURG, TRANSVAAL, South Africa.



JAMES LEFFEL'S
Mining Turbine Water Wheel.

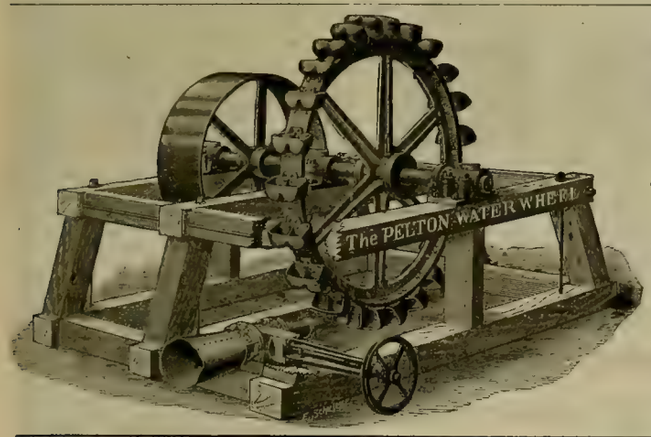
These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

JAMES LEFFEL & CO.,
Springfield, Ohio, or 110 Liberty St., New York.

FRASER & CHALMERS, General Agents, Chicago, Ill., and Denver, Col.
PARKE & LACY, General Agents, San Francisco, Cal.



THE PELTON WATER WHEEL

GIVES THE

Highest Efficiency of any Wheel in the World.

A MARVEL OF ENERGY AND POWER.

Over 600 in use on the Pacific Coast alone, aggregating upwards of 50,000 Horse Power.

It is not only most economical of water, but the most simple and reliable power for Quartz Mills, Compressors, Hoisting, Pumping, or any other purpose where water power can be used.

ELECTRIC TRANSMISSION.

Power from these Wheels can be transmitted long distances with small loss, and it is now being extensively used in this way in all parts of the country for producing both light and power.

☞SEND FOR CIRCULAR. Address:

THE PELTON WATER WHEEL CO.,
120 First Street, - - San Francisco, Cal.

The BUYERS' GUIDE is issued March and Sept., each year. It is an encyclopedia of useful information for all who purchase the luxuries or the necessities of life. We can clothe you and furnish you with all the necessary and unnecessary appliances to ride, walk, dance, sleep, eat, fish, hunt, work, go to church, or stay at home, and in various sizes, styles and quantities. Just figure out what is required to do all these things COMFORTABLY, and you can make a fair estimate of the value of the BUYERS' GUIDE, which will be sent upon receipt of 10 cents to pay postage,
MONTGOMERY WARD & CO.
111-114 Michigan Avenue, Chicago, Ill.

Practical Treatise on Hydraulic Mining.
BY AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, $5, post-paid. For sale by DEWEY & Co., Publishers, 220 Market St., San Francisco.

INVENTORS, TAKE NOTICE!

L. PETERSON, MODEL MAKER,

258 Market St., N. E. cor. Front (up stairs), San Francisco. Experimental machinery and all kinds of models. Tin and brasswork. All communications *strictly confidential.*

"De man wot knows it all is alluz a-makin change, a-buyin' ob experience." The man who does *not* think that he "knows it all" about Pumps can find out a great deal about them in *Grimshaw's* PUMP CATECHISM. By mail, postpaid, $1. Dewey & Co., 220 Market St., S. F., Cal.

THOMAS PRICE'S ASSAY OFFICE,

CHEMICAL LABORATORY,

BULLION ROOMS and ORE FLOORS,

524 Sacramento Street, San Francisco, Cal.

COIN RETURNS ON ALL BULLION DEPOSITS IN 24 HOURS.
WORKING TESTS OF ORES BY ALL PROCESSES.
SPECIAL ATTENTION PAID TO CONCENTRATION OF ORES.

Ores Received on Consignment, Sampled, Assayed, and Disposed of in the Open Market to the Highest Bidder.

Metallurgy and Ores.

SELBY
SMELTING and LEAD CO.,
416 Montgomery St., San Francisco.

GOLD AND SILVER REFINERY
And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

....MANUFACTURERS OF....

BLUESTONE,
LEAD PIPE,
SHEET LEAD,
SHOT, Etc., Etc.

ALSO MANUFACTURERS OF

Standard Shot-Gun Cartridges,
Under Chamberlin Patent.

JOHN TAYLOR & CO.,
IMPORTERS AND DEALERS IN
ASSAYERS' MATERIALS, MINE AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco.

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scorifiers, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we fee confident from our experience we can well suit the de mand for these goods, both as to quality and price. Our New Illustrated Catalogue, with prices, will be sent on application.

☞ Our Gold and Silver Tables, showing the value per ounce Troy at different degrees of fineness, and valuable tables for computation of assays in grains and grammes, will be sent free upon application. Agents for the Patent Plumbago Crucible Co., London, England. Also for E. G. DENNISTON'S Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, Feb. 28, 1889.

In general trade there was more activity the past week than at any time this year. The call does not appear to be confined to any one section, for from nearly all distribution points come fair-sized assortment orders. The two days rains in the past week contributed no little in dispelling the gloomy feelings of some merchants, for now they not only speak more cheerfully, but are disposed to extend trade in localities where fears were entertained regarding the outcome of the crops. The deposit of snow in the mountain ranges is not as deep as is desirable, yet it is of sufficient depth to supply many mining districts with water well into the summer months. Collections are better than they have been, still they are not made as freely as they should at this time of the year. In the local market money is quite close, owing to many capitalists calling in their money so as to avoid paying taxes, while others again having money idle would not put it out for the fear of having to pay taxes on it. Large sums of money were sent out of the State for the same purpose; the latter has caused exchanges on the East to rule very high. After this week, moneys drawn out of general circulation will be put into circulation again, when a lower range of interest will obtain. The call for accommodations is said to be light. The decline in the price of coal is well received by iron workers and manufacturers in general, but the firmness with which iron is held to some extent counteracts the effect of the lower range of coal. In the speculative markets there is more activity in local securities, with Spring Valley water stock the favorite at a decline. It now looks as if the inside is beginning to concentrate the stock they sold at higher figures. In mining stocks there was more active trading with lively fluctuations, with the movements being of a chopping character. The trading was chiefly in the Comstocks, where very important work is going on. While this work promises good results, yet it now looks as if it may be some time before anything very positive can be determined regarding several veins, ledges or ore bodies being run far in some of the mines, and in the meantime it is claimed that a line of assessments will have to be levied. Probably the certainty of the latter causes the more pronounced bear feeling among many of the outside operators. From the other mining districts the news is of an important character, but everything points to the future before the work now going on in the mines will determine their richness in mineral ore.

It is claimed that the Mexican mill will, on tomorrow, commence crushing ore from the Crown Point, Virginia City, mine, but then operators think the ore to be crushed now will not assay high.

At the California Electric Light Co.'s office the writer was informed that the remaining dynamos (four in number) are in readiness to be put in place in the Nevada mill, Virginia City, as soon as word is received to go ahead. Our Virginia City advices report that the two dynamos now in use in the mill could not work, and why the full complement of six dynamos are not put in use, causes considerable surprise, which leads to the impression that the course of the managers of mills is controlled for stock manipulation purposes, for with six dynamos working, 60 stamps instead of 40 will drop on ore, besides allowing the California Panmill to start up.

Advices received to-day from Virginia City are confirmatory of a further improvement in the ore in Ophir, and also of an improvement in Crown Point on the 800-foot level.

SILVER—The market held to fairly firm prices throughout the week. There was apparently more disposition on the part of sellers to meet buyers' views, and in consequence the steamers to sail for China on March 2d will take out fairly large shipments. The disposition to sell was no doubt mainly due to the near approach of tax-assessment day. The very high rates that ruled for exchanges the past week were in favor of silver. After this week it is claimed that they will ease off, for there will be no occasion to send money out of the State so as to dodge paying double taxes. Sales of silver were made the past week at from 93 3-10 to 93 2-5c, and even at 93½c. With more water in the Carson river, it is expected that the output of silver from the Comstock mines will be increased in the near future.

QUICKSILVER—The market continues quiet, but steady at last quoted prices.

LEAD—The movement in pig is chiefly for Alaska canneries. The market is unchanged.

TIN—The market, which was also bare of supplies, was relieved the past week by three vessels bringing tinplate, putting in an appearance. It is said that about all had been contracted to arrive, and that some not under contract was placed at $5.25 to an Alaska cannery. Pig is without change.

COPPER—The market is reported to be settling to steadier prices.

COKE—Arrivals the past week aggregated more than for some time past, but as all received was under contract (some had been resold as often as four different times) the market is not affected, but continues strong at $20 a ton for spot.

COAL—The demoralized market was not bettered any the past week by several vessels laden with Australian putting in an appearance. It is claimed that our coast collieries are handicapped by high freights, they being fully as high, if not higher, from the mines up north to this city than from Australia to this port. This does not appear to be the worst, either, for there is said to be a large tonnage headed toward Australia that must seek this port for wheat charters, owing to light crops in Australia, and they will bring coal for ballast, if not for profit. It is claimed that the output of the coast collieries will be reduced in the near future by reason of the above competition.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Savage, Feb. 23, $16,837; Hale and Norcross, 23, $37,041; Cons. California and Virginia, 23, $56,538; Hanauer, 19, $2500; Hanauer, 20, $20,401; Mt. Diablo, 28, $8029; Peerless, 28, $5143; Hanauer, 21, $2700; Confidence, 28, $15,621.

Mining Share Market.

The stock market has weakened somewhat during the latter part of the week. The following mining companies have been dropped from the list in the San Francisco Stock Exchange for the non-payment of the annual dues: Silver Star, Rock Island, Pioneer, Brophy, Orleans Con., Atlantic Con., Flowery Haywood, Montezuma, Pondere, Champion, Combination and Christy.

The Virginia City *Chronicle* of the 26th inst. contained the following: The snow in the mountains is reported as disappearing very rapidly under the present warm temperature, and an unusual scarcity of water for operating the Carson river stamp-mills must ensue unless another snowfall occurs of greater depth than has yet accumulated. Ore shipments from Comstock mines last week aggregated 5849 tons, divided as follows: Con. Cal. and Virginia, 2459, assay value, $33.50; Savage, 428, assay value, $21; Hale and Norcross, 1081, assay value, $21.78; Potosi, 940, assay value, $20.40; Confidence and Challenge, 790, assay value, $26.40; Justice, 240, assay value, $30; Alta, 220, assay value, $29.75. The bullion yield of the above aggregated about $140,000. Bullion shipments from the Con. Cal. and Virginia mine on the current month account up to Feb. 22d, aggregated $113,378. The February yield of the mine will not fall far short of $300,000.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

THE CALIFORNIA CONSOLIDATED Gold Mining Company, Sierra City, Cal., A. Schubert, President; Alvin Fischer, Secretary; A. Lefler, Superintendent. Divided into 30,000 shares at $1 each. Property comprises two locations. Ore assays $7 per ton, average. Coarse gold, solid rock; vein from 15 inches to 2 feet wide Tunnel No. 1 in 120 feet, and prospects well. No. 2 just begun. Stockholders: Alvin Fischer, A. Schubert, Gus Fischer, F. L. Fischer, Anton Fischer, Fred Fischer. For information concerning stock, etc., apply to F. L. Fischer, Sierra City.

THE BUFFALO CONSOLIDATED GOLD Mining Company, Sierra City, Cal., Ernest Busch, Superintendent. Stock divided into 600,000 shares at $1 per share. The property comprises 5 locations. Ore finely decomposed, carries coarse gold. Size of ledge: Tunnel No 1, 32 ft.; No. 2, 9½ ft. No. 3, 10 ft. Fine black decomposed rock interspersed with white quartz. New 10-stamp mill run by a Pelton Wheel, blacksmith shop and boarding house. Stockholders: Ernest Busch, Hugh Murray, Frank Cook, J. G. Lee, Henry Carpenter. For further information apply to Ernest Bu ch, Sup't, or Hugh Murray, Sec'y.

THE H. H. H. Horse Liniment puts new life into the Antiquated Horse! For the last 14 years the H. H. H. Horse Liniment has been the leading remedy among Farmers and Stockmen for the cure of Sprains, Bruises, Stiff Joints, Spavins, Windgalls, Sore Shoulders, etc., and for Family Use is without an equal for Rheumatism, Neuralgia, Aches, Pains, Bruises, Cuts and Sprains of all characters. The H. H. H. Liniment has many imitations, and we caution the Public to see that the Trade Mark "H. H. H." is on every Bottle before purchasing. For sale everywhere for 50 cents and $1.00 per Bottle.

For Sale by all Druggists.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

EXTENSIVE GOLD MINE FOR SALE.

To be sold at public auction by the undersigned, at the Merchants' Exchange, in the City of Halifax, on Thursday the Fourteenth day of March next, at twelve o'clock noon, that extensive, valuable and well-equipped GOLD MINE known as the Dufferin GOLD MINE, situate on the Atlantic coast, about ninety miles east of said city. Daily mail from Halifax. Telegraph office at Salmon river, four miles from the works. Salmon river harbor never freezes, and is safe and easy of access. The mine embraces 342 areas, each 150x250 feet, all in one block. The entire area measures fifteen hundred feet in width across, and eight thousand five hundred and fifty feet along the lodes. The leases have nearly fourteen years to run, and can at any time be renewed for a period of twenty-one years, upon payment of two dollars per area. Within this area is a belt of veins dipping on each side of an anticlinal. They have been found by tests made on the surface to extend upwards of 4,000 feet The ore has been partially removed to a depth of 200 feet over a distance of about 700 feet, and to a depth averaging about 70 feet over an additional 1,000 feet in length or thereabouts. The veins are of various width, the largest averaging about ten feet of solid quartz.

This mine was discovered in the Autumn of 1880, but was not worked to any extent until the Autumn of 1881. It has yielded up to the end of November, 31,012 ounces of gold from 84,568 tons of quartz, according to the sworn returns made to the Mines Office. The gold can be produced at a cost which will leave a very handsome margin of profit.

The mine is operated by machinery worked by water power, the power being transmitted by a line of wire rope running from the water wheel to the mine—a distance of about 4,750 feet—and lying parallel to the outcrop of said veins, at a distance therefrom of about fifty feet. The Salmon river crosses the property twice. It supplies the hoisting and pumping power, and the same water is afterwards used to drive the crusher. The latter has thirty-eight stamps, and there is ample water power to operate three times that number. Sixty stamps can be operated with present machinery. Of the 120 horse-power existing for pumping and hoisting only about twenty-five is used. There are about 700 acres of well timbered and well watered land owned with the mine. This partly covers the areas, and where it does not immediately adjoins them. It is also provided with a steam plant to operate hoisting gear and pumps in case of accident to the transmission power, a sawmill, sufficient for the requirements of the property, a tramway from the mine to the crusher for carrying quartz, and stables, offices, and boarding-houses, sufficient to accommodate a large number of employees.

The mine is owned and has been operated by a partnership, and owing to the death of one of the principal owners it has to be sold to enable his estate to be settled. A good title will be given.

Terms, ten per cent cash, balance within thirty days from day of sale. The deposit to be forfeited in case the purchaser fails to complete the purchase within that time. Further particulars can be had on reference to N. H. MEAGHER, Q. C., Bedford Row, Halifax, or to JAMES DUGGAN & SONS, Auctioneers, Bedford Row.

SAN FRANCISCO CORDAGE CO.

(A Corporation.)

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

TUBBS & CO.,
611 and 613 Front St., San Francisco, Cal.

SHARES IN A GOLD MINE.

A limited number of shares of Buffalo Con. G. M. Co.—a developed and working mine in Sierra County, California—will be sold, in order to procure additional appliances in connection with the water supply. The mine has a mill and is producing good rock. The shares are non-assessable and held among a few owners, and none of them have been put on the stock market.

Apply to H. WIEDERSHEIM, care Cigar Store, No. 200 Market street, San Francisco, Cal., or by mail to No. 1513 Curtis street, Oakland, Cal.

THE DUCKER PORTABLE HOUSES

Combine all the comforts and advantages of a permanent building with the qualities of Simplicity, Stability, Lightness, Ease of Transportation, Quickness of Putting Up and Taking Down, Ventilation, Heating, and Facility for Cleansing. Equally serviceable for Contractors' Uses, for Sheep and Cattle Ranches, Mining Camps and for Surveyors and Prospectors, Hospitals, Seaside and Summer Resorts, and in all localities where material and skilled labor are scarce, and where it is sometimes desirable to change location. These Buildings can be especially constructed for Hunting and Fishing Camps, Billiard Rooms, Photographers' Studios and Lawn Pavilions. They are built in sections and are put up without the use of screws, nails or any external appliances whatever. Two men can put up the building on ordinary ground in 2 hours' time without skilled labor. Price, $250 to $750. Thoroughly reliable and influential business men only, may communicate with this Company relative to acting as its representative.
Address DUCKER PORTABLE HOUSE COMPANY, 32 Nassau St., New York.

For Mining and Irrigation Purposes.

Also Sawmill Machinery.

EXCLUSIVE AGENTS FOR THE PACIFIC COAST OF

HEINE PATENT SAFETY BOILER and MACBETH STEEL PULLEY.

AGENTS FOR THE PACIFIC COAST OF

BRYAN'S ROLLER QUARTZ MILL,

The most perfect Roller Mill made, for the following reasons:

1. It is cheaper.
2. It is more durable.
3. It crushes a larger amount of ore with less power.
4. It amalgamates a larger percentage of the gold.
5. Its "clean-up" is quicker and fuller.
6. It is portable, requires no frame-work, and is ready for the foundation as it leaves the shop.

Full Descriptive Circulars of any of the above sent on application.

OFFICE OF THE CANDELARIA CONSOLIDATED MEXICAN MINING CO., SAN DIMAS, DURANGO, MEXICO, October 25, 1888.

Risdon Iron Works, San Francisco—GENTLEMEN: Our Company has been operating three of the 4-foot Bryan Roller Quartz Mills, one of which has been running steadily for three years, one for two and one for one year. Our quartz is very hard; we crush through a No. 60-mesh screen. Our mills run 55 revolutions per minute, and each crush through 60-mesh screen 12 tons in twenty-four hours; through 50-mesh, 15 tons; and through 40-mesh, 18 tons. This proportion has been continuous. One set of Dies will crush from 1500 to 1600 tons. One set of Tyres will crush 1500 tons. One ring plate will crush from 2200 to 2300. The mills require very little attention. At our mill an ordinary "peon" earning one dollar per day has complete charge. In regard to sliming, in comparison with stamps by reason of the discharge surface and the continuous agitation by the scrapers, a MUCH less amount of slimes is created. A three years' experience teaches me that, in every respect, the mills are a complete success and of material benefit to the mining world. They can be set up and running in 48 hours, and can be dismounted in the same time and removed to wherever desired. Ours were packed on our mule trail over as difficult a road as any in Mexico. As a gold amalgamator, it is unequaled by any mill now in existence.

Yours truly, D. M. BURNS, Superintendent.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

SAN FRANCISCO, SATURDAY, MARCH 9, 1889.

VOLUME LVIII. Number 10.

British Columbia Mines.

We had a conversation the other day with Dr. T. J. Jones of Victoria, B. C., who is interested in mining properties in the Nicolai Valley region. There are some very good claims there which make a fine showing. The ore is all "concentrating," and carries silver and gold. They can work the year round in that region, which is much similar in character to the Grass Valley district in California. There is plenty of wood and water, and coal has been found 12 miles from the mines.

Dr. Jones states that the operations of George Henderson, who was connected with the Star and Planet mines, Nicolai Valley, and the Foster M. & M. Co., Lillooet district, have rather given the country a "black eye." He was manager and part owner of these mines, but ran them in debt and made a failure of the work. He was supposed to be an expert miner, but had very extravagant ideas and did not succeed in putting the mines on a paying basis. The men were not paid, and other operations have been retarded in consequence. The man referred to has left and gone East somewhere. The British Columbia mining people are of the opinion that the district referred to will come out all right in the end, though at present matters are somewhat dull.

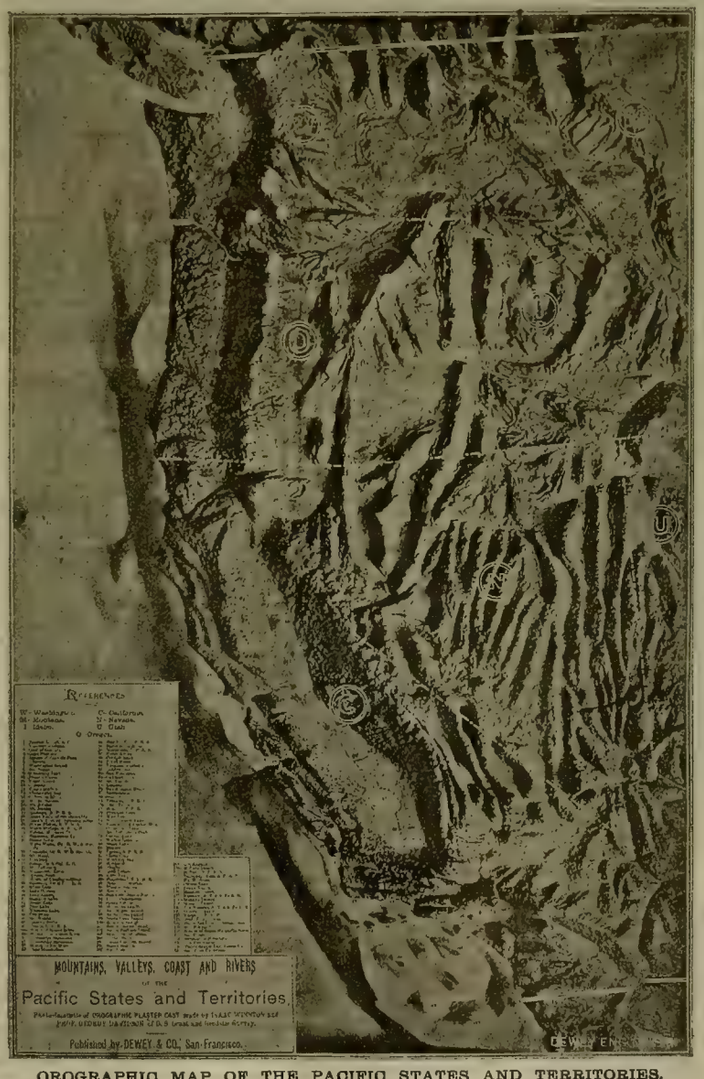
MINES AROUND DOWNIEVILLE.—A correspondent writes us that prospects are brightening for Downieville, Sierra county, several valuable quartz ledges having been found during the past year. Three 20-stamp mills will be put up in the spring close to town, for the Oxford (more familiarly known as the Good Hope), owned by H. T. Briggs, H. H. Purdy and others; Gold Bluff, the property of A. Van Slyke (where a 10 stamp mill has been crushing ore with princely returns for months past); and the Wheeler, being developed by Eastern capitalists under the supervision of John Hughes. The Bald Mountain Extension (drift mine) may soon be yielding good dividends. The upper tunnel, three miles by the wagon road, northwest of Forest City, is in one-half a mile and Supt. Meikle believes within about 426 feet of the channel.

ACADEMY OF SCIENCES.—At the meeting of the Academy of Sciences on Monday the Hon. Lucius A. Foote read an interesting paper on "Corea," to which country he was sent by the United States Government when the first commercial treaty threw open the ports of Corea to the world. A paper was also read on "California Earthquakes from 1769 to 1887," the contribution of Prof. Holden. The following new members were announced: Townshend S. Brandigu, Waldemar Lindgren, Volney Rattan, James E. Mills, L. Belding. The death of two members, Seth Cook and Dr. Jules C. A de Tavel, was reported.

CHROMATIC ABERRATION IN TELESCOPES.—A dispatch from New Haven, Conn., says: Professor Hastings of the Sheffield Scientific School, after long experimenting, has succeeded in so combining two glasses, the composition of which is a secret, that chromatic aberration in a telescope has been corrected. This will make telescopes from 10 to 30 per cent more powerful, and new telescopes will probably include Prof. Hastings' principle.

IRON SMELTING ON PUGET SOUND.—About $700,000, most of which has been supplied by San Francisco capitalists, has lately been expended in an iron-smelting plant erected on the shores of Puget sound. The company engaged in the enterprise has the finest and most powerful engines and machinery to be had for this purpose. It has also a fine reduction works is on the southwestern shore of Port Townsend bay, and is called by the suggestive title of Irondale.

THERE are about 140 workmen employed on the Stanford University and the mausoleum now, and three carloads of material arrive from the quarry every day. The buildings have



OROGRAPHIC MAP OF THE PACIFIC STATES AND TERRITORIES.

town site, including a good water supply and excellent wharfage facilities. The furnace is operated with a hot-air blast, and charcoal is used for fuel. Four grades of iron are made, the finest having brought in the markets a higher price than the best grade of Scotch pig iron sells for. As proof of its superior quality the company is now supplying the Southern Pacific Co. with iron for the manufacture of car wheels, and it is well known that car wheels require the very best iron to be had anywhere. Although the furnace is turning out 40 tons of iron a day, it will require several months to complete contracts now running with the railroad company. The location of the reached a state from which some idea of their massive grandeur can be obtained. None of the structures are entirely finished, however, although foundations have been completed wholly around the quadrangle. In addition to the work done thus far on the university proper, there are three other large structures which have been erected. One is the boiler-room with a huge towering smokestack, to be seen for miles. Another is the engine-room, and the third the work-building.

CHAS. A. ASHBURNER, the "oil expert," is examining the oil-fields of the southern part of this State.

Pacific Coast Relief Chart.

We give herewith a miniature copy of the large photoplate relief map which we made direct from a relief model in plaster, illustrating the mountains, valleys, lakes, rivers, etc., of the Pacific States. The large map is 19x24 inches in size. An orographic model has never before been made of the Pacific Coast, and the chart shows a facsimile of it. It gives a much better idea of the topography and orography of the region than can be gained by Mercator's projection maps. The idea of a bird's-eye view is conveyed, while at the same time the correct proportions are preserved. The continuous chains and isolated ranges of mountains are shown with the adjoining valleys and watercourses.

The great backbone of the coast, the mighty Sierra, stands prominently in view, dividing the coast region from that of the great interior.

The configuration of the ranges and mountains can be traced in such a manner that the routes of the principal railroads can be seen as they take advantage of the natural passes.

The coast line is an interesting study in itself. A portion of the ocean-bed is shown, so that the abrupt rising of the land is plain. In places are deep submarine valleys, and again the shoaler submerged land is apparent. The bays, harbors, inlets, river-mouths and islands are also figured.

Numbers are placed on the chart, and a corresponding index gives the names of the principal mountain peaks, lakes, rivers and cities. The course of any large river may be traced winding through the mountains to the sea. This chart will give any one a very excellent idea of the surface features of California, Nevada, Oregon, Washington, and part of Montana, Idaho and Utah. It is printed on heavy paper suitable for framing, and is sold to subscribers of the PRESS for 10 cents by Dewey & Co., publishers.

The "Mining and Scientific Press."

Any one connected with the mining or other industrial occupations on this coast cannot fail to find matter of interest and value in this and other numbers of the MINING AND SCIENTIFIC PRESS. The various departments of the paper are carefully made up of practical matters useful to all. Our correspondence has increased of late, as has our advertising patronage. The advance in both these features is well illustrated in the present number. Many readers will find matter of interest to themselves in the advertising columns as well as in the reading matter. As the oldest mining paper in the United States the experience of the editors and publishers is of value to the reader. We hope our old subscribers will bring the PRESS to the attention of those who would be benefited by becoming regular patrons.

THE Reading Iron Works, Penn., have failed, with liabilities of over $1,000,000. The company owning the works was one of the largest in America.

J. V. WILLIAMSON, the Philadelphia philanthropist, who gave $12,000,000 for a boys' school for manual training, died this week.

THE sum of $214,862 was disbursed in wages during February to the miners on the Comstock.

CORRESPONDENCE.

We admit unindorsed, opinions of correspondents.—EDS.

Central Idaho.

EDITORS PRESS:—The great Salmon-river region in Central Idaho promises to be the scene of much mining activity the coming season. A great many rich prospects were discovered last year, and on these the owners will do work this summer.

In this region the mines contain a variety of ores, but there seems to be a preference for free-milling gold ores, and it is in this character of ore that this region promises so well.

A great many of the quartz veins found hereabout contain the yellow metal in good-paying quantities.

The writer has examined a number of fine, rich samples, showing gold plentifully, and these ore specimens are from large, well-defined contact and fissure veins. There is a very extensive quartz region here in this Salmon-river country that has long been neglected. Several millions in gold dust were taken out of the placer deposits, and strange to say, very little has been done with the rich gold-quartz lodes in the immediate vicinity of these placer gulches.

It seems many of the old placer miners were prejudiced against gold-quartz mines; they worked out the richest of the creek beds and quit the country. It seems, too, as though the thought never occurred to them that the very source of their placer gold was the quartz veins cropping out all through the mountains. These early miners gathered the dimes and left the dollars. But we cannot blame them; it takes machinery to get gold out of quartz. No difference how rich the quartz is, it still requires machinery. At that time there were only trails over the country—machinery was out of the question. Now the "iron horse" goes rolling along within sight and hearing of this long-slumbering wilderness.

On the very borders of this great mountain mineral region, there are a few small mills at work crushing the gold out of some of the gold veins, while yet the central and richer portion is still in its primitive state. It is a splendid field for the prospector—all that region between the Rocky mountains and the head of Boise river and from Wood river to the Cœur d'Alenes, more especially in the vicinity of the Salmon river itself. This Salmon river is about 500 miles in length, runs in shape like a horse-shoe, and from its source in the Sawtooth range to its mouth in Snake river, along its whole length, gold may be washed from its sands and gravel beds. And again, nearly all the tributaries, especially the larger creeks, wash in gold from the various slate and granite mountains. Down on the river, about 100 miles below this place (Salmon City), several Chinese companies have been mining two or three years, and it is known that they have secured a good lot of gold-dust. The gold on or near the river-bed is usually quite fine, but occasionally some good heavy shot-gold is found. In this great mountain section drained by the Salmon, there are hundreds of creeks that have never been prospected, and as it is all more or less a mineral country, there is a good show for a number of these gulches to be good in gold. Such has been known about Leesburg, Florence and Warren's, and there is no reason why some more of the same character may not be found. The country is not one-tenth prospected. It is known to be a quartz country wherever examined, and hundreds of these quartz lodes are rich in gold.

Some 40 miles below this place, right on the bank of the river, is the great property known as the Grunter, a gold-quartz lode 60 feet wide. Several thousand tons of the Grunter ore have been worked in the small mill on the ground. The ore averages $27 per ton in gold, but only about half that amount is saved with the mill. There are no pans, settlers or roasters connected with the mill, hence the loss. It is a magnificent gold property, badly mismanaged. Near by, and on the same vein, is the Kentuck mine, which has been a fair and steady producer for the past five years. It is also free ore, except the sulphurets, which should be roasted. There are a score or more other claims in the vicinity that are opening up well. Several of these properties will likely change hands this year and be extensively worked. More soon about other districts hereabouts. CHAS. F. BLACKBURN.

Salmon City, Idaho.

Bad Mining Laws.

EDITORS PRESS:—Occasionally I read articles in your valuable paper in regard to the inefficiency of our present mining laws. The present law prevents the development of mines, and offers a premium for fraud. Men hold claims year after year without doing any work on them. Perhaps it would be better for every man who desires a quartz claim of 1500 feet to pay $100 per year for five years and then receive a patent for his claim. It costs $100 to buy 20 acres of mineral and $400 for red tape and technicalities, besides $500 worth of trouble in solving the many conundrums necessary to comply with the complex mining laws.

The honest mossback Granger has his land ommissioner, the people their railway commissions, but the miner is left out in the cold to take care of himself. The miners have only produced a few thousand million out of the ground and made California what it is.

I believe the miners are as much entitled to a commissioner of mines to represent their interests and pass upon the mineral and non-mineral land as a county is to a board of supervisors. A commissioner of mines could decide by investigation as to the quality of the land claimed by parties as agricultural, and prevent men obtaining title to lands for agricultural purposes that would not raise a white bean, simply to defraud the Government out of the mineral land. Some one has said all men are liars; if they are not, some one is mistaken; but I do know that in this district there are many men who have taken the non-mineral oath when they promised and told parties beforehand, if they got the land they would sell them the mining claims on it, or let them work on shares. I know one man here that, before he applied for the quarter-section of land, had been for years trying to bring a ditch of water to work the gravel on the land, and after he obtained a patent for the land, he sold it, but reserved the quartz ledges and mineral. I think you can in your valuable paper show the present weakness of the mining laws and the absurdity of the new one that Senator Stewart is trying to have passed. We want a plain, simple law, easily understood and complied with. The average miner is no Solon. Another grievance is if all the mineral land is taken for agricultural purposes, miners find it difficult to obtain fuel and timber.

I believe it would go far toward having proper representation if the miners of this State would hold a convention in San Francisco, and take such action as would protect what is today and will be one of the greatest interests in this State. MINER.

White River, Tulare Co., Cal.

Grub Gulch and Potter Ridge Mining Distr ct.

EDITORS PRESS:—This camp has been overlooked by mining men, and I think it my duty to inform the public through your paper of the facts as near as I can. Having followed the business for nearly 20 years in various localities, I think I have the experience to give a proper description of the camp and mines.

The mineral belt of different formations is about five to six miles wide, and is running in a northwest and southeast direction, passing through the entire width of the county. The main belt is composed of four different belts of formation of different slates, running parallel with each other, making four contacts between the different formations. That makes it favorable for well defined and permanent ledges. The first belt on the west side is a pure black slate and joins on to the granite one. The contact is what is known up North as blue fissure lead. It is thought by some mining men that it has not been found or discovered south of Grass Valley. This is a mistake, for it is here as plain as day on the contact between the black slate and granite, but it is a little different in its character here from what it is in Grass Valley, on account of the formations bearing so regular. There are no cross formations to cut the fissure off, or cause big "blows," bunches or pockets. The fissure in this locality runs for miles very regular, and it hardly forces its way to the surface; so any one finding it on the surface, no matter how small, it will be advisable for him to sink on it, for the ledge will come to its proper size in depth. It is very regular when it comes to a certain level. Of course the higher the ground the more liable the ledge is to be pinched as far as this kind of a ledge is concerned. This ledge is a sulphuret ledge, there not being much free gold in the ledges after the depth of 30 or 40 feet is reached. Some places where the ore comes to the surface, of course the sulphurets are oxidized, and that leaves the gold free, so it will show in a horn spoon.

There are quite a number of mines on this fissure, and every day's work done on them they improve, encouraging the owners. The next belt to the east is a serpentine formation that contains ledges more bunchy and irregular than the formation first mentioned, and the gold is more of a free nature. The next formation to the east is slate. There are liable to be some very rich deposits of free gold ore in this, and perhaps some good mines

The last belt on the east side of the main belt is a spar slate, or of that nature, with big spar dikes running quartering with the formation. This belt is liable to have some extremely rich deposits of ore in it, and perhaps very extensive. The blue lead will bring this county to the front, for every day's work that is done puts a brighter face on our prospects.

Grub Gulch, Fresno Co. C. M. WARD.

A PROSPEROUS RAILROAD.—The earnings of the Southern Pacific Company for 1888 make an unusually good showing. The gross earnings were $48,850,208; expenditures, including interest on bonds, $44,901,381. The earnings of the Central Pacific division were $15,848,862, and expenditures $14 882,032, leaving a profit of $962,830, lacking $397,170 of reaching the guaranteed rental of $1,360,000. Deducting the loss from the earnings of the other divisions gives the net earnings of $3,550,656, or 3½ per cent on the outstanding stock of $100,000,000.

Yield of Comstock Mines.

The Assessor of Storey county reports the product of certain Comstock mines for the quarter ending December 31, 1888, as follows:

	Tons.	Average.	Bullion.
Alta Con	946	$24 62	$23,330
Challenge	1,375	16 75	21,406
Chollar	2,835	14 00	38,131
Confidence	6,195	17 87	105,071
Con. Cal. & Virginia	32,278	21 50	690,845
Hale & Norcross	4,280	21 00	90,016
Savage	5,202	12 50	66 423
Yellow Jacket	3,388	7 70	25,836
Totals	57,089	$18 77	$1,071,648

The above lacks returns from the Gould and Curry, Occidental and Overman mines to be complete. The Virginia *Chronicle* thinks the additions from these mines and the product of the mills in the Six-Mile canyon would swell the total for the quarter to $1,250,000. The same paper thought the product of the Chollar and Savage, omitted from the previous quarter, would have made the total $1,175,900, instead of $1,064,200. We do not see why the complete list is not given from quarter to quarter. Where official figures are possible, they are more satisfactory than estimates. Five of the mines for the last quarter of 1888 worked their ore at a loss, despite the favorable assay values. The ore from the Alta Consolidated mine averaged $24.62, and yet the net cost of production was $8908 above the yield. The Chollar worked $14 ore at a loss of $13,559 above the yield. The Hale and Norcross lost $18,785 on the $21 per ton ore worked in the last quarter of 1888. Savage had $12.50 per ton ore, and yet its product of $66,423 or the last quarter of 1888 was made at a net loss of $40,673 Yellow Jacket has been milling ore right along for upward of a year at a loss. The report of this mine for the last quarter of 1888 is as follows: Product 3388 tons ore, yielding $25,836; average yield per ton, $7.70; cost of extraction, reduction and transportation, $54,270; cost of production above yield, $28,414. Stockholders would have been better off if no ore had been worked from this mine for the past two years. But, of course, there is a profit in the milling, and such of the stockholders as are interested in the milling get good returns and are anxious to see the extraction of ore kept up We can see how it is possible to so grade the ore sent to the mills to make such a low average that only the mill-owners will be benefited But why $24 ore, or $21, or $14, or even $12 ore cannot be worked, except at a loss, we do not quite understand, though of course there are good reasons for that state of affairs.

The quarterly reports of the Storey county Assessor, so far as made public, in a consolidated form, show the yield of the Comstock mines for the calendar year of 1888 to have been as follows:

	Ore Tons.	Bullion Yield.
Alta Con	946	$23,330
California	142 419	3,322 262
Challenge Con	3.123	55,267
Chollar	9 000	134 434
Confidence	34 409	725,871
Hale & Norcross	36,678	949,745
Kentuck	1,027	13,055
Potosi	3,050	56 461
Savage	5,972	66,423
Yellow Jacket	28,618	211,651
Total 1888	264 582	$5,558 409
Total 1887	283,300	4 402 417
Total 1886	268,786	3 430,526
Total 1885	223,004	2,895,249

In making up the statement for 1887, a year ago, we had occasion to say that the indications pointed to as good a yield in 1888 as in 1887. The result shows a less quantity of ore milled, but an increase of over $1,000,000 in the bullion product. From the present outlook, we think 1889 will hardly be a duplicate of 1888 in the bullion yield of the Comstock mines, though any day may show up discoveries that will put an entirely new phase to the whole business.—*Bulletin.*

Photographic Processes.

According to Prof. Wood, the most valuable characteristic that can at present be claimed for photography in its scientific uses—or at least the one by which the most remarkable powers have been exhibited—is in the capacity possessed by the sensitive surface of storing up feeble impressions of light, so that an image is produced by the long-continued act of vibrations too feeble to have any effect until they have been allowed to impinge upon the plate for a considerable time; the experience of astronomers in this respect need only be referred to, as in point. On the other hand, the light rays, if of sufficient energy, can, as is well known, produce their due effect in a time which, to human appreciation, seems infinitely small; thus, photography observes and records the successive positions of a rapidly moving object, whereas to the eye the successive movements are by the persistence of human vision blended into a sort of general average, as in the case of a galloping horse—or lost in confusion, as in that of a rapidly spinning wheel. The photographic plate may also be said to have a greater range of vision than the eye—it is affected by rays to which the eye is quite insensitive, and thus, by its aid, cognizance can be taken of and rays observed beyond the limits of the visible spectrum, of the highest and the lowest refrangibility. As to the amount of detail which is set before it, the photographic lens is, of course, indifferent—a large extent of surface can be observed and its detail at once recorded. In a short series of exposures the lines of a spectrum, which it would take months or years to map by hand, are recorded with an accuracy which the hand could never hope for—the exposure of a single plate to the heavens giving greater and more trustworthy results than six months' toil would formerly have yielded.

Liability of Mining Directors.

In the suit of Emanuel Eyre against Joseph Marks et al., directors of the Gould & Curry Mining Company, Judge Hunt granted the defendants' motion to strike out all that portion of the complaint which relates to the penalties said to be collectable from the directors of mining companies who fail to post statements from superintendents at specified dates.

In rendering his decision Judge Hunt said: "The complaint alleges that the directors failed to perform their duties in accordance with the Act of 1880, Section 1, which requires that they shall cause to be posted in the secretary's office the receipts and disbursements of the company for the current month, and to file with the secretary the itemized accounts of his receipts and disbursements, the question presented here being whether or not the directors should be held liable for any failure or omission other than their own.

"It will be observed from the reading of the Act in question there is pertinent ambiguity in it.

"In the first place it says that the directors shall cause to be posted in the office of the secretary, at certain given times each month, an itemized account of the superintendent's receipts and disbursements, and in the event of a failure so to do these directors jointly and severally shall be liable to a penalty of $1000.

"It seems to me very clear that it was never intended by the Legislature in the passage of this Act to make the directors of the companies liable or responsible for a penalty in the omission of the duties of officers other than themselves. It would not be right or just to hold that directors of a mining company should be liable to a penalty for failing to have a superintendent file with the secretary itemized accounts of his receipts and disbursements at the exact time called for in the Act referred to.

"Directors cannot be held responsible for delay in the transportation of mails or other matters which might occur at any time, and which, according to plaintiff's idea, ought to work against defendants, and make them liable for a penalty of $1000.

"Therefore, in keeping with these views, I think the allegations of the plaintiff, referring to the delinquency of the directors for failing to see that the secretary omitted to post the facts, should be stricken from the complaint. It is so ordered."

The same ruling was made in the seven other cases brought by Mr. Eyre against other mining company directors for similar alleged neglect of duty.

NEWBERRY-VAUTIN REDUCTION WORKS.—When Mr. J. W. Higginbottom was here several months ago, looking over the field for the purpose of informing himself as to the inducements to erect reduction works at which ores and concentrates would be treated by the Newberry-Vautin process, he secured an option on a tract of land on the railroad about one mile east of town. Mr. Higginbottom advises the *Daily Union* from Omaha, under date of Feb. 16th, that the London syndicate, for which he was operating, has authorized the completion of the purchase, and has deposited the money with Wells, Fargo & Co. to his credit. From this it would appear that the London company has decided to erect works in this district, which will be the only works in California using the Newberry-Vautin process. The intention is to build the works on a scale to handle all the business not only that this district may afford, but from all other quartz-mining districts of the State, and it is expected that the business will grow into large proportions. As stated in these columns heretofore, the Newberry-Vautin process has long since passed the experimental stage, and is now conducted successfully in different parts of the mining world, the results of the process showing that it saves a larger percentage of the precious metals than any other practical working process. The London company has now large reduction works at Denver, Col., and is crowded with business all the time. The establishment of the proposed works at Grass Valley will be of untold benefit to the mining interests of this district.—*Grass Valley Union.*

TIMBER ON ALASKA LANDS.—A case of some importance was decided before Judge Sabin and a jury in the United States Circuit Court yesterday. The suit was brought by the United States against William Thonagal to recover 214,000 feet of Alaska spruce cedar, or the value thereof, estimated at $5000, the said lumber having been illegally cut and removed from Government lands. The lumber was shipped and brought to this city as the property of the North Pacific Trading & Packing Co. on the schooner Gem, of which the defendant Thonagal was master. The jury found a verdict for the plaintiff for the sum of $3145.35, the appraised value of the lumber.—*Chronicle.*

ALL the white miners in the Comox (B. C.) coal mines have struck on account of the introduction of Chinese, and the mines are now being worked by Chinese alone.

Astronomical Affairs.

Likelihood That Southern California's Big Telescope Will Not Be Built Very Soon—The Paris Lens Maker.

Reports from Los Angeles are to the effect that no authoritative directions have yet been given to Alvan Clark relative to the proposed 40-inch telescope on Wilson's peak. Mr. Clark spent some time there lately, climbed the peak, gave a favorable judgment respecting the location, and awaited orders. He gave the trustees of the University of Southern California to understand that he stood ready to undertake the task and even went so far as to name his price for furnishing the desired lens and photographic and spectroscope attachments. Less than $200,000 was his figure for the difficult work, but he came away with merely a "preliminary order—whatever that means," said he, in speaking of the matter. He is very confident of his ability to carry out the work, but those who are well qualified to speak say the chances are few that the great telescope will ever be made. A French glass manufacturer, Mantsur, who has practically succeeded to the business of the Feils, has offered to make Mr. Clark glass of any desired size. He is considered by Clark and others to be much better qualified for his work than was the elder Feil, who achieved world-wide fame in this direction. Mantsur has just cast a plate of glass fully 40 inches in diameter, which he will exhibit at the Paris Exposition. Clark has already an order for a 40-inch lens for a telescope to be built by one of the South American Republics, and it is very likely that this glass cast may be used for this work.

Captain Fraser, who superintended the construction of the Lick Observatory, is said to be a candidate for similar work at Wilson's peak. He was present at the recent survey of the site by Mr. Clark, the University trustees and others, and hoisted the American flag on Willow peak during impressive ceremonies and speech-making. The endowment of Mr Spencer is sufficient to secure little more than the telescope, and how much else a well-equipped observatory needs the Lick trustees can testify. And after buildings are in shape the observatory must have scientists and an income to support them and carry on the work.

It is understood that Ambrose Swasey of Warner & Swasey of Cleveland, who constructed the mounting of the Lick telescope, will come out here soon. His visit is by request, in reference to certain features of the pier of the Lick Observatory, which are not considered entirely satisfactory by the astronomers.

The Geodetic Survey.

The Los Angeles Base-Line.

About four months ago Prof. George Davidson of the Coast and Geodetic Survey left this city for field service in Los Angeles county. He has been in camp all the time, and having completed his labors, returned to the city last week. He went South, with a party of assistants, to establish a base-line in that region, similar to that located some years ago in Yolo county. The base-line in geodesy is one actually measured, from which all other distances in the survey are calculated, and upon which all triangulation depends for accuracy. The Yolo base-line is used for all purposes on the northern coast, and the line just located will serve as a check on possible errors in calculation from the Yolo base. The present final line does not differ more than 10 or 15 yards at any point from Captain Lawson's line, made some time ago. The results obtained are satisfactory, and Prof. Davidson is confident that no divergence greater than one-fourth of an inch in the surveyed lines can be found.

The established base is northeast of Los Angeles, extending northwest and southeast, between Norwalk and Anaheim. Its length is 17,496 meters, or 10⅞ miles, within 10 meters of the length of the Yolo base-line. Over a month was required to prepare for the actual surveying work, and then the rains of November and December interfered somewhat.

The officers of the party in order of rank besides Prof. Davidson were Captain Lawson, Messrs. Morse, Nelson, Edmonds and Westdahl. In addition there were 16 men who had served from time to time in various surveying parties. There was little chance for recreation or anything but close attention to the field-work. The camp day began at 5:30 A. M. and closed at 6 P. M. A standard field bar, with which the measuring bars were often compared for accuracy, formed part of the equipment. This standard bar will go to Washington to be compared with the official measuring standard there kept.

The ends of the established line were marked by vaults and surface monuments. The vaults or piers are of brick and stone, six feet square, and reach fully five feet below ground. On the surface is a large granite cube in which is set a silver bolt. In time these surface marks will be replaced by monuments of granite about ten feet in hight, suitably inscribed. The upper end of the line is about one mile northeast of Norwalk, and the lower limit two miles southwest of Anaheim.

THREE veins of rich copper ore have been found in Napa county, on the ridge between Berryessa and Spanish valleys.

Gold and Silver.

The Director of the Mint, in a report on the production of gold and silver in the United States during the calendar year 1888, says:

"The gold product was 1,644,927 ounces, of the value of $33,175,000. This is about the same as in 1887, being an excess of only $175,000. The silver product was 45,783,632 fine ounces, of the commercial value of about $43,000,000 and a coining value of $59,195,000. This is an increase of 4,515,327 fine ounces over the product of 1887.

"In addition to the product of our own mines, some 10,000,000 ounces of silver were extracted in the United States from foreign ore and bullion, principally Mexican. The total refined product of the United States in gold was 1,777,877 fine ounces, and in silver 53,128,698 fine ounces. The value of gold deposited at the mints during the year, not including redeposits, was $41,496,410, or including redeposits, $48,794,988. The foreign material comprised in this was $7,055,046. The amount of silver deposited and purchased was 35,512,789 standard ounces of a coining value of $41,323,973, exclusive of re-deposits.

"Coinage at the several mints during the year was: Gold, $31,380,808; silver dollars, $31,990 833; subsidiary silver, $1,084,773; minor, $912,201; total, $65,318,615. The import of gold bullion and coin was $11,031,041, and exports $34 619,667. The loss by export was $23 587,726. Import silver amounted to $21,592,062, and export $29,895,222. The loss by export was $8,303,160."

AN ELECTRIC BLOWPIPE.—The ordinary method of electric welding by passing the current through the points to be fused together are not convenient for all purposes, and Prof. Samuel Sheldon of Harvard University suggests what he believes would be better for many cases. The pole of a powerful magnet strongly attracts or repels the electric arc, which may by this means be driven out sideways into a point very similar to the point of flame projected from an ordinary blowpipe. At the end of this point the heat is intense, being sufficient to melt large copper wire instantly and to fuse any of the metals. It would serve admirably for welding, and a slight alteration would fit any arc lamp to perform the double function of lighting and welding.

Boring and Firing Stumps.

Mr. Wm S. Smith, writing from Greenville, Or., to the *Oregonian*, has the following suggestions to make with regard to clearing land of stumps:

I have read in your issue of February 1st an account of how to blow out stumps, together with several parties' experience, and I thought it might not be out of place to give my eight years' experience, or, at least, what I have learned in that time of how to burn out stumps and to clear up fir land generally.

In the first place, I bore and burn down the trees. For this purpose I use a common two-inch auger, 2½ feet long, for the upper hole, and a crank auger, of the same length, 1¼ inches in size, for the lower or draught hole. I bore pretty deep, then fire with vine-maple coals and fir bark and blow with a bellows. It also pays to bore another hole lower down, so when the fire burns down to it it will save chopping out for draught and is much easier done. This is the time of year for this kind of work, for not only does the fire not spread through the timber, but you have it ready to burn when dry weather comes, and nearly everything except the large logs will burn up. The best of these are generally used for fencing, firewood, etc.; the rest, or such as are necessary, I generally use to burn the stumps out with, which I do in the following manner:

I first dig a trench around the stump from three to four feet wide, according to position of the roots, and 1½ feet deep; then put in a day or two boring and firing logs. A good man, if he uses a crank auger, and a boy or two to fire for him, can bore and fire 60 to 80 places in one day, according to size of timber. They should be bored from six to eight feet apart, according to size, so as to be easily rolled on to the stump.

The next move is to bore and fire the stump, which should be bored about at the line of where the dirt ordinarily touched it. I bore into the main roots the two-inch auger on top, and the 1¼-inch crank for the draught. By using a two-inch at the top they are more easily fired, for they are generally pretty hard to get started, but perseverance and plenty of bark will win; and when the place is burned out, or both holes burned into one, then roll in the logs previously burned into their places and in the trench and on top and continue to do so, cleaning off all ashes and dirt every morning. It will take from three to four days to burn out a six-foot stump, and when it is out it is gone.

The dirt from the trench will fill the hole where it stood, level, and the plow won't touch it; whereas, if they are blown out, you still have the stump on hand, also the logs used in burning them with, no dirt to fill the hole, and at least $1 out for explosives, to say nothing of the danger. After a careful estimate I find I can burn them out in the above way for—six-foot stumps, $1; smaller ones, proportionately less. This I claim to be the cheapest way for farming lands; but where grading is required blowing out is no doubt the best, for you neither have to fill the hole nor destroy the stump afterward. Farmers at this season of the year generally have more time than money to expend on stumps, and will, I think, find the above the cheapest way, unless some one has a better way, in which case I for one would like to hear from him, for I am at present improving these fine days at this business.

SCENE IN A CHINESE THEATER.

In Chinatown.

The tourists who visit this city are always anxious to visit Chinatown and see the Mongolians in the surroundings of their daily life. The people who live here, and are familiar with the Chinese and their habits, do not consider this visit so much of an amusement. Few people, in any event, care to make the trip through Chinatown more than once, if they visit the underground dens and other unpleasant places there to be found.

Some of the buildings in Chinatown are quite picturesque, notably the temples, restaurants and theaters. The better class of Chinese decorate and enrich their surroundings in a curious and interesting way. We give on this page an engraving which shows a picturesque resident of the quarter—a Chinese actor arrayed in his peculiar gorgeous costume. White people often visit the restaurants and theaters, and they are kept cleaner than other buildings in Chinatown.

A MEDICAL MYSTERY.—A well-developed case of rabies is believed to have recently been developed from wounds from fish-hooks in New Orleans. The story is told as follows: A middle aged man named Frank Woods called at the Charity hospital for treatment. He said he was a fisherman and was suffering from terrible pains in his head, throat and chest. He acted strangely, and every once in a while would clutch at his throat. Shortly after going to bed he was seized with convulsions and showed every symptom of hydrophobia. He was chained to the bed, and when he recovered sufficiently to talk said that he had never been bitten by a dog, but had often run fish hooks in his hands and had often been finned by a fish. About midnight he grew rapidly worse. He became so violent that notwithstanding his chains it required two men to hold him. His hands were not tied, and while in the convulsions he would grasp his throat and emit sounds that greatly resembled the growl of a dog. The next morning Dr. Miles stated that the patient was suffering from a well-developed case of rabies. The report does not give the result.

PICKING FROZEN GROUND.—Mr. F. H. Shelton says: "I took off from over the gaspipe some four or five inches, just a crust of earth, and then put a couple of bushels of lime in the space, poured water over it and slacked it, and then put canvas over that, and rocks on the canvas, so as to keep the wind from getting underneath. Next morning on returning there I found that the frost had been drawn out from the ground for nearly three feet. You can appreciate what an advantage that was, for picking through frozen ground, with the thermometer below zero, is no joke. Since then we have tried it several times. It is an excellent plan if you have time enough to let the lime work. In the daytime you cannot afford to waste the time, but if you have a spare night in which to work, it is worth while to try it."—*Scientific American.*

THE ALASKA BOUNDARY.—The report of the Interior Department (Ottawa, Ont., Canada) contains the following with reference to the Alaska boundary, at present a subject of dispute between Canada and the United States: The observations of William Ogilvie, in charge of the survey in Yukon district, have not yet been completely reduced, but an approximate circular shows that the boundary is nearly 90 miles below the point where it is marked on the United States maps. This is of great importance, as the line passes through the best gold-bearing districts yet discovered in the country.

ONE HUNDRED AND FIVE collieries are now open in India, which, among them, mined nearly 1,400,000 tons of coal since 1886. It is not very long since the chief Indian Government geologist said he was prepared to eat all the coal that was ever found in India.

"SPERRYLITE," a new discovery, is said to be the first mineral yet found containing platinum as an important constituent other than the natural alloys with various metals of the platinum group.

A QUARRY of red sandstone, of fine quality for building purposes, is being developed at Ione. The rock is a pinkish red, and the quarry promises to be extensive.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

FROM PLYMOUTH.—Cor. Amador *Ledger*, March 2: Twenty stamps at the Pacific mill are making music for the town pounding out the much-needed root of all evil, and giving employment to quite a number of our working people. The water supply is rather short, and rain is needed to supply the power for the mines and also to make the crops grow. The New London mine is going to have a mill put up as fast as the machinery and material for building it can be got on the ground, so we hear. Mr. Ballard and a force of men are expected up from San Francisco this week to start the work. Mr. James has started up work on his mine, the Lady Bedford. He intends to run a tunnel at the 300-foot level, and commence stoping out rock. The Leventon Gravel mine, east of Plymouth, is turning out to be a regular bonanza. They have got their tunnel run through to the main channel of the hill, and have fine prospects in coarse gold, $5 and $10 to the pan being very frequently met with, and sometimes as high as $25 are panned out. The claim looks as if it would be everlasting, and this is the first tunnel that has ever been run into the hill. All other mines in this place are lying idle at present.

DRYTOWN,—The Potosi mill has been idle a few days on account of scarcity of water, but started up again this morning with David Dyer as mill boss. The Gover mill is also idle. They ran out of rock while changing the steam-power to a water hoist, which proved a failure on account of insufficient pressure to run both mill and hoisting machinery from the same pipe.

GOVER.—*Ledger*, March 2: Supt. Call was in Jackson this week, and stated that the trouble with the water-power recently put in at this mine had been greatly overestimated. He says the mistake was made in not taking into account the friction in over a mile of pipe. Mr. Knight is confident that he can get it to work all right. The work of draining the shaft is in progress. All the ore that has supplied the mill under the present management has come from above the 500-foot level. Below that the shaft has not been freed from water. It is 1000 feet deep, and the intention is now to see the bottom and explore the lower levels. It will take six weeks to complete the drainage of the shaft. The mine has been doing remarkably well of late. Some of the ore has been immensely rich. Forty pounds of quartz was sold some time ago for $1000, to a jeweler. In the richness of sulphurets the Gover stands at the top. As much as $9000 has been received from sulphurets in a run of two months, the sulphurets running from $165 to $200 per ton. This is said to be without a parallel for 20 stamps. The ore carries about two per cent of sulphurets. The rock varies considerably in its yield of gold, running from $3 to as high as $10 and $12 per ton.

AMADOR GOLD MINE.—At this property work is going ahead with increased activity. Graders and millwrights are at work on the new hoisting and pumping plant. The ore bin is put up, teams are at work hauling rock for the masonry work, and it is expected to have the works in operation in a month's time. The ditch is nearly finished. Work on the reservoir will be started next week. The company has just finished timbering the 450 station and resumed sinking. The underground engine is expected to arrive in a few days, when it will be put at the 250 level to do the work now done by the hoisting works at the south shaft. Then the surface hoist will be taken away to allow the millwrights a better chance to put up the big hoisting works. Afterward the underground engine, which will be run by compressed air, will be used to sink winzes.

INTEREST SOLD. — Frank Littlefield has sold his interest in the Alice mine, above Big Bar bridge, to Mr. Petrie, one of the partners, for $15,000. H. T. Tripp was offered the same sum for his share, but refused it. The property is paying well, better, in fact, than the owners expected.

ALPI.—Bids were opened last Tuesday for sinking the shaft 50 feet below the tunnel level. The contract was awarded to W. T. Robinson, J. E. Hageman and E. F. Henderson at $4.75 per foot, contractors to furnish powder, caps, candles and fuse.

MISCELLANEOUS. — Ten stamps of the South Spring Hill mill are to be started at once on rock from the Talisman, for a test crushing.

Calaveras.

COPPEROPOLIS.—*Prospect*, March 1: Considerable work is being done on the copper mine at Copperopolis. New hoisting works are being constructed on the main shaft and a six-inch Jack Head pump is being put in. The Copper Co. is constructing a building about 30 by 60 feet to be used as a storeroom and offices. Within the last year several new buildings have been constructed. We learn from Mr. Ferson that from 500 to 600 tons of copper ore have been shipped from the mine during the last year. The coming season the Copper Co. expects to ship about 1000 tons of ore per month. At the present time there are about 110 men working in and about the mine, 50 of whom are employed in the mine; the others are wood-choppers, teamsters, etc. At present good copper ore is being taken out of the seventh level of the mine.

El Dorado.

THE BALTIC DISTRICT.—Placerville *Observer*, Feb. 26: While we are not now authorized to mention names, we have had it from good authority that several men of vast capital are going earnestly to work, within a short time, to make developments in the Baltic district, a few miles north of Grizzly Flat, and during the coming spring and summer not less than a quarter of a million dollars will be expended in that district in machinery and developments. Some of the most promising prospects in the county are found there, prominent among which are the Big Bonanza and the Varozza mines. It is now in contemplation to build a good wagon-road from Pleasant Valley, across Camp creek, to the Baltic, for the more convenient transportation of machinery and supplies to this new district, and from the present outlook, we are looking for some important developments to be made there. The proposed road would shorten the distance about 14 miles. The Stillwagon mine, upon which work is being vigorously pushed, has been bonded to a San Francisco company, and a five-stamp mill is being erected.

ALPINE. — Georgetown *Courier*, Feb. 28: Supt. Morton informs us that he is going to resume work on the Alpine within the next few days. The present machinery on the mine will be retained and used.

TUNNEL.—A tunnel 50 feet long has just been run by Gibbs & Buchler, under contract, on the ledge on east side of Dark canyon, at Bright Hope mine. The ledge is three feet wide and good milling ore. The tunnel will be continued 50 feet farther, when a crosscut will be run to develop the ledges lying to the east. It is known from surface prospects that the two ledges to the east are much larger. To run in on the west ledge, which was lower down the canyon, and then crosscut, was deemed the most practical thing to do. This development is encouraging, as it proves that free milling ore continues to a depth of fully 300 feet below the shaft on the Bright Hope mine.

Fresno.

NEW GOLD STRIKES.— Fresno *Expositor*, Feb. 27: The mining industries in this camp have progressed very rapidly in the last six months. The Surprise mine, owned by an English company, is looking better than it ever has. The company has been sinking for the past three months. The mine is 520 feet deep now, and a drift is run 600 feet to the west on the 400-foot level, and it shows a fine and continuous body of ore from four to six feet wide. There is a drift run also on the east side of the main shaft, 400 feet, on the 300-foot level, showing a fine body of ore also. This mine is under the superintendency of J. B. Little, who is a practical miner. The company has a 25-stamp mill running day and night on the mine, and have about 50 men in their employ. It is a fine property beyond doubt. The next principal mine of the camp is the Gambetta, owned by Mr. Haley. This is supposed to be the richest mine in the county. Mr. Haley has the largest sized Huntington mill on the mine, and has kept it running day and night for the past five years. The mine is 450 feet deep and has several hundred feet of levels run on it. The mine employs from 15 to 20 men the year round. The Nob Hill, owned by Mr. Rhyne, is looking splendidly. Two arastras are running on the ore, which is packed on animals from the mine to the arastras, a distance of one mile. Two rich strikes have been made lately, one by A. W. Pool and the other by Joe Swanstrom. The strike made by Pool is an exceedingly rich one, near the Fresno river. He has opened the ledge in four different places, and it shows about the same in all of them. He has taken out rock that is nearly half gold, and considerable of it, too. Swanstrom's mine does not show much specimen rock, but it is very regular and will go $50 per ton. The ledge is two feet wide and has a 40-foot shaft on it. The two prospects are close together—about a half mile distance between them. There is no doubt but what those two strikes will prove to be good mines in a short time and draw the attention of mining men to this camp.

COPPER MINES. — Madera *Mercury*, Feb. 27: Few people in Fresno county are aware of the existence of one of the richest beds of copper in California, but which is as yet undeveloped. It is situated about 12 miles northeast of Madera on the large ranch formerly owned by H. C. Daulton. Several years ago, when Mr. Daulton disposed of this land, he reserved 60 acres on which are many rich ledges of copper ore, and he rightly anticipated that it would be a valuable possession at some future time. Mr. Daulton allowed others to become interested in the property, and it is now owned by a corporation composed principally of Fresno capitalists. This week a San Francisco syndicate is negotiating for the purchase of these mines with the intention of immediately commencing the work of development.

Nevada.

CHAMPION.—Nevada *Transcript*, Feb. 26: The Champion quartz mine at this city never before looked so well as it does now. Another level is being sunk for, and when it is developed the milling capacity will be increased by five stamps and two Frue concentrators. Supt. Vincent's management of this property has been notably successful from the time he took charge of it.

DERBEC.—At the Derbec drift mine there is now better gravel being opened than for a long time previously. Eighty-five men are steadily employed. Preparations are being made to rewash the tailings which have been impounded to this end. The payment of dividends will be resumed at an early date, and there is already enough pay dirt in sight to yield five or six. Supt. Galavotti displays much ability and care by the manner in which he handles this extensive property.

YOU BET.—The cement mining company operating at You Bet has every prospect of opening one of the best properties of that character which has existed in the county at any time. Said an old resident of that locality: "From all the information to be obtained it is safe to predict that You Bet mining district is about to recover its old-time prosperity."

Placer.

IOWA HILL.—Cor. Placer *Herald*, Feb. 26: Mining circles are rather quiet just now. The reports from the Pioneer are very encouraging. It is said to be paying very well, although handicapped by a scarcity of water to run all the stamps. I believe there have been only 15 running until very recently. The ore is very good and the force of men in the mine is being gradually increased. Red Point continues to pay well. Watts Bros. at Strawberry flat are at present working only four men, but in the near future their force will be enlarged. The new tunnel at the Eclipse quartz mine, near Cottage Home, approaches completion. The Hohrman mine, at Prospect hill, is working splendid. I hear that the gravel is just yellow with gold, and an average of $12 per carload has been obtained by washing. With a mill this ought to produce at least $30, if not more, per load. The Morning Star has kept up a steady output of gold for the past year or more, so that one is hardly justified in saying much else of this mine than to call it a good-paying property. The contract for extending the main tunnel is going on satisfactorily. The water supply of this mine is short, and if no rain falls this winter, more than has already fallen, the water will be scarce next summer. The Washington is working a small force of men, but there is no water in the ditches which communicate with this mine to wash the gravel. I hear, though, that they are getting good pay by rocking the best of the dirt. I am very much afraid that this place will suffer greatly from want of water unless the storms of March are unusually severe. Armstrong Bros. & Miller are running their tunnel night and day, and hope soon to reach the long-looked-for prospect. It is reported here that the Hogsback mine is shut down until more favorable weather for starting a new tunnel. Also whispers of another great tunnel at the Cape Horn next summer. The New Basil has started a tunnel on their mine, and I am told that as soon as possible they will push it to completion in short order. This tunnel is to do away with the hoisting works now employed at this mine.

BELL'S MINE.—J. E. Spencer is putting up a whim on A. O. Bell's mine, near the Rock Creek school-house, and will sink a shaft 200 feet in depth to test the richness of the ledge. The *Herald* expects to hear of rich developments, as this ledge has been prospected for a distance of 3000 feet on the surface, and rich ore has been struck at every point.

FOREST HILL. — Placer *Republican*, Feb. 26: Wm. Dodge, Jr., of Forest Hill was down yesterday. He reports that he still has 14 men pegging away at the Baker divide mine, but since last September all work has been done by hand, on account of the lack of water. The main tunnel of the mine is in 3300 feet, but all recent work has been done in drifts from the upraises, and is in the nature of prospecting. The company hopes to make some provision for water in the near future.

BELCHER.—Georgetown *Gazette*, Feb. 28: The Belcher quartz mine in Placer county, near Ralston's, formerly known as the Whitman claim, is being opened by Jos. Ward of this place. He has completed 70 feet of tunnel within the last six weeks, and expects to reach the ledge before the end of March. The lode is 10 feet wide on the surface, and shows a good prospect.

Plumas.

A GOOD MINE.—Plumas *National*, Feb. 28: The Lucky S. mine, situated above Indian Valley, owned by J. Hardgrave, E. D. Hosselkus, J. W. Thompson and others, is paying exceedingly well. J. W. McCartney, an experienced quartz miner, is superintending the mill and under his management the rock is paying about $20 per ton. The ledge is increasing in width as the work is pushed forward and everything indicates a rich and permanent mine.

RICH STRIKE. — A rich quartz ledge has been found in Gold valley, a short distance south of Mohawk, by a man named Andrew Gibson. We have been informed that some of the rock taken out is marvelously rich.

Shasta.

STARTED UP.—Redding *Democrat*, Feb. 23: The Lost Confidence mill at Iron Mountain started up last Saturday and is now running night and day. The Texas & Georgia mine has received and put in place their new machinery—the Dodge cannon-ball outfit—which works to a charm. They now work up 20 tons of ore a day. The sulphurets are still shipped to Selby in San Francisco, however. The Walker mill in Old Diggins district has again started up. The proprietors will put a pipe into the river soon, when they will add about ten stamps to their present capacity. The old Florida and Josephine mines, under the management of the Walker brothers, are developing into one of the best dividend mines in the State. They are more than satisfied with this purchase, and it is known that their monthly shipments of bullion are large. The contract to build the road from the Uncle Sam mine to Kennet has been let to Lee Fader, and work will begin immediately. The new tunnel which is to tap the main ledge in this mine has also been contracted for. It will be 600 feet long. F. Warner came down from the Clipper mine Monday morning, bringing a nice bar of gold, cleaned up from a trial run of 12 tons of ore through a Kendal mill. He went to 'Frisco yesterday morning and intends to purchase a five-stamp mill, which he will erect alongside of the Kendal. After a run of eight days in the Gladstone mill on Cline gulch, a $1500 bar was cleaned up last Saturday. The ore of this mine is milling an average of about $20 a ton. Mr. Thomas Lowden is reopening the old Highland mine near French gulch, and recently struck some good ore in a new drift run from an old tunnel. This is one of the oldest quartz mines in the county, having paid well years ago when worked by a local company. It is now owned by Sheriff Hopping and Mr. Lowden, and if the present developments continue favorable, the old mill will be moved and rebuilt on Clear creek, a short distance from its present location.

MINING OPERATIONS.—Redding *Free Press*, March 2: Joseph Parker returned from San Francisco last Monday. He informs us that he has succeeded in forming a company in Kearny county, Nebraska, for the purpose of sinking to the bottom of an old channel that crosses Dry creek near Horsetown. Noah S. Batcheller has organized three companies in Kansas and Illinois to operate in the same vicinity. They expect to commence operations about May 1st. Three families are coming on at once with the companies and two more will arrive shortly afterward.

Sierra.

ANOTHER RICH FIND.—*Tribune*, March 1: Another good find has been made at Hog canyon in the way of an immensely rich quartz ledge. The ledge is about three-quarters of a mile northeast of the Buffalo mine, and it resembles that rock in many respects. A gentleman, who ought to know, told us yesterday that he believed the rock which comes from the newly developed ledge to be even superior to the average rock taken from the Buffalo. Knowing the quality of the Buffalo rock, we can imagine the richness of the new prospect. Our informant says that from no part of the ledge opened up can a piece of rock be broken off that does not show some free gold. Messrs. Geo. McGee, Hugh Murray, John Sorocco and Felix Yoell are the locators of the ledge. Geo. McGee and Felix Yoell are at present at work sinking a shaft.

Siskiyou.

HUMBUG GULCH.—Yreka *Journal*, March 2: A man named Kincaid and his partner, two strangers, have been at work in the old Joe Long quartz ledge on Humbug gulch, west of Yreka, and took out a piece of quartz last week, from which they pounded $60 in a mortar. They are continuing work in the ledge, and expect to realize a rich and permanent mine of great value. McCook & Co. are busy getting out quartz from their mine on Humbug creek, and expect to take out considerable money this season. Their mill is also kept running every day, crushing rock for the Hegler Bros.' new ledge, lately discovered on Old Craggy. The Hegler boys and Bruce Aldrich are also getting out quartz at their claim on the north fork of Humbug, and will commence crushing as soon as warm weather melts the snow and ice to supply water for their batteries and steam engine, their mill and mine being located in the shade of the mountain, where the hot sun has but little influence, until we have warmer nights and rains to help out. The Ashland *Record* is informed by a gentleman from Hornbrook that the upper drift in the Black Jack mine to strike bedrock in Cottonwood canyon, this county, is in 175 feet. In the lower tunnel, which is being used to drain the water, good paying gravel was discovered. This mine is owned by Geo. Barr & Co., and M. Sullivan and Conductor Morgan are interested in it. They recently refused $8000 for the claim from San Francisco parties. Miners from Hungry creek, in the Siskiyou foothills, near the Oregon boundary, have been at Hornbrook lately with some very rich specimens of quartz rock containing more gold than quartz.

San Bernardino.

CITY CREEK MINES.—*Index*, March 2: Public interest in the City Creek mines has dropped below zero, as no returns have ever been made public regarding the working of the ten tons of ore sent to National City. The *Times-Index* is able to announce officially that the bottom has not dropped out of the mining boom of City Creek. About the time the carload of ore was sent to National City there arose dissensions in the management of the work where the ore was to be worked. The result was that the ore was not properly handled, and yet a good-sized brick of bullion containing gold and silver was obtained. This brick has been sent to San Francisco to be refined and the owners expect returns from the same soon. The owners of the mine have so much confidence in their property that they are now putting in small, temporary works at Colton, at a cost of about $600, to further test the rock. Mr. Chick, of the National City works, will have charge of the works at Colton, and before many days another carload of rock will be worked, when the full report will be given to the public.

SAMPLING WORKS ASSURED.—Colton *Semi-Tropic*, March 2: Sufficient money has been raised to erect the sampling works in Colton. They will be erected on the vacant lot southeast of the Pioneer lumber-mill, work having been commenced this morning. It is expected that as soon as it is demonstrated that good ore can be found in sufficient quantities, reduction works will follow. The claims on the Jurupa ranch are reported to be making a good showing. Some of this ore will be among the first to be tested by the new sampling works. Mr. G. H. Chick will be manager of the concern.

San Diego.

STONEWALL.—Julian *Sentinel*, Feb. 26: Old experienced miners, men who ought to know, say that the Stonewall promises to be the richest mine on the coast.

SAN DIEGO.—In all probability the San Diego mine, east of town, will be opened up shortly.

Trinity.

NEW RIVER MINES.—Trinity *Journal*, March 2: J. D. St. Clair of New River was in town this week, and reports that camp in a most flourishing condition. Ladd & Clements are taking out rich rock from the Mountain Boomer, which they are crushing in their stamp-mill. They are running tunnels and developing the mine and have their property in fine shape to handle. The mine has been bonded to an Eastern company for $60,000. Some surveying will have to be done on the mine before a transfer can be made. This winter's snow has hitherto prevented a survey. A large force of men is at work on the Ridgeway. A tunnel is being run to tap the ledge at a depth of 400 feet and is now in over 200 feet. The tunnel is being pushed rapidly, eight-hour shifts working night and day. The ledge at the bottom of the shaft is well defined and is high-grade ore. When the mine is well opened it will be one of the best in the northern country. An English company has bought an interest and is supplying the capital to develop and work the mine. Nicholson, who has leased the Hard Tack of Ladd & Clements, is taking out first-class rock; he cleaned up $2750 from 15 tons of ore. That is good enough ore to satisfy any miner. This mine is an extension of the Ridgeway. The owners of the Sherwood mine are running tunnels, developing the mine and taking out ore. They are not crushing now, owing to the scarcity of water. In the Uncle Sam, Boles, Gulick & Heney are running a tunnel to tap the ledge at a depth of 200 feet; this will give them plenty of stoping ground. Smith Brooks, the veteran prospector and one of the fathers of New River, is running a tunnel on the north side of the Mary Blaine to tap the ledge. G. V. Heley has struck a big prospect on Eagle creek which bids fair to equal any of the older locations. There are over 500 feet of tunnels in the Hunter mine, and ore enough in sight to take a year and a half to crush. The ore averages $40 a ton. On the whole the prospects for a prosperous season's work in the camp are most encouraging. There are about 150 men there and the camp looks better than ever. The advent of capital is all that has ever been needed to show the worth of the mines, and from now on the camp will steadily increase in wealth and numbers.

DEADWOOD.—Trinity *Journal*, March 2: The Deadwood mining camp is gradually improving and the mines showing better all the time. The Brown Bear Co. has the best mines in the camp, and under the superintendency of T. J. Houghten they are paying larger dividends than ever before. The McDonald Bros. and Franck are doing well, running their 10-stamp mill constantly on good ore. Barney McDonald, the superintendent, is an experienced miner, and is making the mine pay handsome dividends.

THE QUARTZ OUTLOOK.—Although the gold yield from our placer mines will be considerably curtailed on account of the dry season, yet we can safely predict a large increase in the output of our quartz mines over last year. With the completion of the East Fork wagon-road, work on which has already begun, several mills will be erected and put into operation before the summer is over in the East Fork camp and the output of bullion will be largely

increased. New River, which lay dormant last summer, has made a fresh start and very lively times are anticipated. Capital has found its way in and will soon display its power in increased development and a steady shipment of gold. Ballychoon has also emerged from the obscurity of last year and work has begun in earnest. There are good mines there, and they will make a good showing this season. Deadwood is holding its own as one of the richest camps on the Pacific slope. News also comes in of promising strikes made in different parts of the county, so there is every reason for asserting that this year Trinity will take a huge step forward in her quartz interests.

Tuolumne

RIVER MINING.—Tuolumne *Independent*, March 2: J. R. Moffit has already commenced getting ready for his river-mining season in the Tuolumne river, about a mile below his bridge. He is also working on his new process for treating ores. He expects to get into his river mine rather earlier than usual this summer. It is said that Dave Oliver and Geo. W. Nicol have leased the Smith vein, and will proceed to develop it. It is the upper vein of three, the under one being the Bonanza. Instead of following along right over the Bonanza pockets, Smith has been branching off. The new parties will follow the vein over the Bonanza and endeavor to find pockets near the surface.

NEVADA.

Washoe District.

BALTIMORE.—Virginia *Enterprise*, March 2: Are still hoisting some good ore from the 338 level.

HALE & NORCROSS.—The face of west crosscut No. 1 on the 400 level still shows stringers of rich quartz. The south drift from the west drift on the north boundary is now advanced 41 feet. More and better ore is found in it than was seen last week. On the 500 level the south drift is now advanced 141 feet. The upraise and stopes above this level are looking well and are supplying the usual quantity of good ore. The 600 and 700 stopes are still looking and yielding well. On the 1300 level quartz carrying some metal is being found in the north drift. During the past week 900 tons of ore, averaging $25 19 a ton, was sent to the Mexican mill. Bullion on hand and previously shipped, $52,746 78.

SAVAGE.—The stopes on the 400 level are improving as regards the quality of ore extracted from them. The several prospecting drifts are looking well. On the 500 level ore is being extracted from the old stopes. East crosscut No. 3 on the 600 level is also yielding paying ore. During the past week 480 tons of ore were sent to the Rock Point mill which assayed $21.33 a ton.

CON. CAL. & VA.—Milling ore is being taken out on all the levels from the 1400 down to the 1950. The best ore and the largest deposits continue to be found on the 1650 level. Are shipping the usual amount of ore to the Eureka and Morgan mills. The average of the assays will be about the same as last week.

CHALLENGE.—Good progress is making in the drifts joint with Confidence, both on the 300 and 1300 levels. They have encountered quartz carrying some metal. The little ore at present being extracted is good, the average assays being $24.73 a ton. The ore goes to the Brunswick mill.

CROWN POINT.—No. 1 west crosscut is out 43 feet in a mixture of porphyry and quartz. The north drift on the 600 level is out 61 feet in porphyry showing streaks of quartz. Have started a north drift from the bottom of the 700 raise, which is out 32 feet in quartz giving low assays.

CONFIDENCE.—Are shipping to the Brunswick mill 450 tons of ore a week, the assays of which average $24.73. Good progress is being made in the drifts joint with Challenge on the 300 and 1300 levels.

CON. IMPERIAL.—On the 1100 level east crosscut No. 2 still continues in quartz and vein porphyry. The work of repairing the main north drift on this level is making favorable progress.

CHOLLAR.—The exploring drifts are finding some good ore. The Nevada mill is running well, the power being one-half transmitted from the Pelton wheels on the Sutro tunnel level.

BELCHER.—The north drift on the 200 level is out 530 feet. The drift from the bottom of the winze on the 1100 level has not yet connected with the raise from the 1300 level.

OVERMAN.—Are taking out about 330 tons of ore a week, which is being worked at the Vivian mill. There is nothing new in any of the exploring drifts.

OCCIDENTAL.—On the 300 and 350 levels much ore of milling value is found. A contract has been let for a 20-stamp mill with concentrating machines.

NORTH OCCIDENTAL.—Some good ore is being found on the 400 level, and quartz showing metal has been cut on the 250.

UNION CON. AND MEXICAN.—The north drift from the Ophir on the 1465 level has reached the Union Con. south line.

SIERRA NEVADA.—The exploring drifts and raises are making good progress, but as yet nothing of value is seen.

OPHIR.—The drift from the bottom of the winze is in milling ore, but it is over the line in Con. Cal. & Va. ground.

UTAH.—The exploring drifts on the 600 level are in vein material carrying some metal.

NEW YORK.—Good headway is making in the north drift on the 800 level.

ALTA.—The mill is running steadily on ore from the 800 and 1100 levels.

JUSTICE.—The mill is running steadily and the mine is looking well.

YELLOW JACKET.—Only exploring work is being done at present.

SCORPION.—The usual progress is making in the 300 crosscut.

ANDES.—Are progressing well in the reopening of the 175 level.

BULLION.—Usual exploring work in progress.

Golconda District.

ADELAIDE COPPER MINE.—*Silver State*, Feb. 26: The Adelaide copper mine at Golconda is fast proving the theory of its owners, that it would become richer in the precious metals as greater depth is attained. At the surface the ore assayed from $6 to $8 in silver per ton. At its present depth, 82 feet, ore assaying 17 per cent copper and 40 ounces in silver is found, with every prospect of still increasing. The shaft is fitted up with one of the most economical but efficient hoisting rigs in the State.

Paradise District.

CREDIT MOBILIER MINE.—*Silver State*, Feb. 26: Albert Lay says the Credit Mobilier mine is now being worked somewhat extensively, and is producing rich gold-bearing quartz. It is owned by A. M. Sadorus, who has worked it at intervals for years. Some specimens taken from the mine have literally been covered with gold. The mine is located about 26 miles east of north from Winnemucca, and about 16 miles from Golconda.

Pioche District.

PIOCHE.—*Record*, Feb. 26: The Pioche Con. Co. has had men working for several weeks on the 8th and 10th levels of the Raymond mine, crosscutting for the ledge. The work on both levels is encouraging and stringers of high-grade ore are already encountered. The prospects of opening up valuable ore bodies at these points are very favorable, and if the theory entertained of the ledges at this part of the mine proves correct, there is room for a bonanza.

Tuscarora District.

BELLE ISLE.—*Times-Review*, March 2: West crosscut from north drift, 250-foot level, extended 21 feet. Rock in the face looks more favorable.

COMMONWEALTH.—100-foot level: No. 1 winze from drift running north from south end line has been sunk 13 feet, showing a small seam of high-grade ore. West intermediate drift from No. 4 chute has been extended six feet, and continues to yield rich ore. Drift running east from same chute is also turning out fine ore. South drift from No. 8 chute has been extended 15 feet; about 15 inches of good ore. 150-foot level: No. 3 winze has been started from east lateral, south; has been sunk three feet, exposing fine ore.

GRAND PRIZE.—400-foot level: West drift on the old vein extended seven feet in a strong vein but low-grade. Face of east drift from north crosscut advanced 13 feet, showing a four-foot vein, two feet of which is $500 ore, balance low-grade. West drift extended 18 feet, vein being larger, but low-grade. Face of north crosscut has been advanced 11 feet through a favorable looking formation.

NORTH BELLE ISLE.—North drift from the bottom of No. 1 winze, 400-foot level, extended 17 feet. The upraise south of the Queen line, 300-foot level, has been connected with the line upraise. An upraise has been started at the south end of the intermediate drift, below the 300-foot level.

FOUND TREASURE.—Some cleaning up of the drifts in the 150 and 200-foot levels has been done. No work of importance will be done, except to keep the water out, till supplies for sinking the shaft another hundred feet can be procured.

NAVAJO.—Work has been suspended for the present in No. 4 south drift, and an upraise started 70 feet south of the 350 stopes, which shows some good ore. The stopes are looking well and are turning out the usual quantity of ore.

COMBINATION SHAFT.—The combination shaft has been sunk and timbered 19 feet. Rock in the bottom shows harder. North drift from the Commonwealth line extended 22 feet.

NEVADA QUEEN.—The stopes continue to yield about the same quantity of concentrating ore. Concentrating works are running steadily and concentrating good ore.

ARIZONA.

HILLSIDE.—Prescott *Courier*, Feb. 25: We heard a gentleman remark the other day that Jack Lawler of the Hillside was naturally lucky, and as proof, said that shortly after the discovery of his famous mine, he let a contract to Joe Howell to sink so many feet, Joe to have the ore he took out. He selected his ore, which ran about $200 a ton, and threw aside a great quantity which he considered too low grade to handle, and finally sold it to Lawler for a mere song, which Lawler bought in good faith, not having any idea of its value. Imagine his surprise and joy on bringing some of it to town and finding that it ran $500 per ton. Of course this looked like luck, but Jack never waited for luck, but went forward with a strong arm and stout heart to hew his own way. There is a fine selection of samples from this mine in County Treasurer Waddell's office, all selected within the last week. There can be seen a red-looking ore that runs $1100 to the ton, and some green-looking rock that runs $480 in silver and 30 ounces in gold. Below the water-line the ore is all sulphide, while that above the water-line is chloride. The greater depth attained the larger becomes the ledge. As regards richness, there is no difference between the chloride and sulphide ore.

HARQUA HALA.—Sim Powell, an old mining friend of the *Courier*, called on us a few days ago, and said he had just returned from the Harqua Hala district, where Stein & Co. have two good mines and Chloride Jack one; that there are lots of California and Colorado prospectors in the country who have money and good outfits, and that there is a tremendous field for the prospector to operate in. Mr. Powell is a partner of Wm. Vanderbilt in some promising gold, silver and lead properties below the new Walnut grove dam; says our prospectors can find no better country for their business than right around home; that it is good enough for him and he means to stand by it.

BRITISH COLUMBIA.

KOOTENAY MINES.—*Colonist*, Feb. 26: Mr. Harry Anderson, mining recorder at Nelson, Kootenay Lake, who arrived here on Tuesday, furnishes us with the following news: The Hall Brothers on Mineral Mountain have been running two shifts on the Silver King mine, and are reported to be in a fine body of ore. Three miles west of them the Tough Nut is being worked by Morrow and Dolan. They report striking a fine body of ore, assaying as high as 400 ounces of silver per ton. The Poor Man, on Eagle Creek, is being worked by Nail & McDougal. Dr. LaBau & Co. report very good ore in large quantities in their various claims.

HOT SPRINGS CAMP.—A. D. Wheeler has been running two shifts on the Gallagher all winter sinking a vertical shaft and is now driving for the ledge. The Number One is being worked by Mr. G. Wright, who has been running a tunnel all winter to tap the ledge. The Little Donald, owned by Davenport and Stevens, has been worked all winter, sinking on an incline out of which they have been driven by water. The Krao, owned by A. D. Wheeler & Co., has also been worked by a few men, following a very rich chute of ore, which was followed until the water compelled them to stop work, leaving the incline on a large body of ore, averaging 180 ounces silver per ton. The Now Then, owned by McGovern and Cap Hayward, adjoining the Crow Fledgling on the south and on the same ledge as that and the Krao, also shows a great quantity of fine ore. The above claims are those on which most of the work has been done through the winter. A number of others have, however, had a small amount of work done on them, nearly all making good showings, among which may be mentioned the Maestro, Banker, Spokane, Kismet, and Ayesha, the last two being adjoining claims on the same ledge. On the whole, all join in saying that this camp will prove to be one of the richest in the Northwest.

COLORADO.

THE MOLLIE GIBSON STRIKE.—Denver *Republican*, March 2: The Mollie Gibson at Aspen still leads. The best of the rich chute as so far developed proves to be embraced in about 15 feet along the vein, but an upraise shows that it improves in the roof. This upraise has been run about three feet and has developed wonderfully rich ore. Much native silver is found and the dirt that falls on the floor is like stuff from a retort. The manner of working is to drive up alongside of the ore and then gad it off. In this way the finest specimen of ore ever seen in this camp, or for that matter in any camp, was taken down last evening. It was broken late and brought over to the office in the evening. The wonderful specimen weighs a little over 300 pounds and will run, as a whole, close to 10,000 ounces to the ton. A piece from the point where the gad was driven in assayed 20,325 ounces. On one corner is a mass of pure silver that must aggregate five pounds, and all over the great boulder the pure metal is plastered. There is not a square inch in which the rich sulphide does not show, and right through it the long way runs a streak, 1¼ inches thick, of the solid metallic stuff that runs over 20,000 ounces. The piece was not weighed, but good judges put the figure at 300 pounds, and it will probably exceed it. The value of this single piece of ore is estimated at $1500.

DAKOTA.

FROM RUBY.—Deadwood *Pioneer*, Feb. 26: The Eclipse company has let a contract for another 50 feet of tunnel. R. E. Love goes up to-day to personally superintend the work. The contractors on the Imperial company's tunnel have completed 75 feet. A further distance of 25 feet will be run to tap the ore body, about 60 feet under the shaft on top of the hill, where ore was first struck. The ore in the top of the shaft assayed from $20 to $28 per ton. Croppings of the vein are seen all around on the same level as the drift, and when the ore body is encountered it will demonstrate a depth of 60 feet of ore. This is the stock of which 30,000 shares were sold last week to a well-known mill-owner up gulch.

IDAHO.

NIAGARA.—Ketchum *Keystone*, Feb. 26: A fine development has been recently made by the lessees, Messrs. Cary & Howe, in the Niagara mine in the Boyle mountain district. They have exposed in their mine a continuous ore chute 60 feet in length, carrying a strong vein of an excellent quality of ore. Some two or three other mining properties in the Boyle mountain district are also being worked under leases, all of which, we understand, are meeting with good results.

SMOKY.—In the Smoky mining district active operations have not been started as yet. There has been quite a force of men kept at work in the Silver Star mine during the winter, but as to the present prospects and condition of the mine we have been unable to ascertain anything. There have been of late vague reports circulated concerning the outlook of this important mining property, but it has been difficult to get at the facts.

EAST FORK.—Flattering accounts come from the East Fork locality and every one there is beginning to make preparations for a vigorous mining campaign the coming season. News was received yesterday that a rich strike had been made in Domski's Venus mine. The vein is reported to be from four to five inches wide, of gray copper ore, running from 800 to 1000 ounces of silver per ton.

STRIKE.—It is reported that a fine strike has been made by Messrs. Shaw & Jacobs, lessees, in the Olympia mine, up Bassett gulch. Parties who came down from the mine on Wednesday stated that one man in one of the openings of the mine is breaking down over a ton of high-grade ore per day.

MATTIE.—The lessees of the Mattie mine on Trail creek are feeling greatly encouraged by the present looks of the mine. It is said that they are encountering ore now and then which runs up into the thousands.

EMMA AND LAST CHANCE.—Wardner *News*, Feb. 26: Development work continues on the Emma mine, giving employment to 13 men. The tramway is daily utilized in conveying lumber and other material to the mine, and also in moving ore to the bin which has a capacity of 300 tons. The mill will resume work about the first of April.

SAN FRANCISCO.—Work is progressing most favorably on the San Francisco mine, where a force of 15 men is busily engaged under the superintendence of E. C. Ray. A new tunnel has been started 100 feet below the old workings, and other development work will be commenced immediately.

FAY TEMPLETON.—Preparations are making for the renewal of work on the Fay Templeton mine. Important alterations and improvements will be made in the mill. Four Frue vanner concentrators manufactured by Fraser & Chalmers of Chicago were shipped from that city on the 16th instant, and are expected at the mine by the end of next week.

MONTANA.

THE CHAMPION MINE.—Butte *Miner*, Feb. 27: It was learned yesterday on the authority of E. P. Mills of the Champion Con. that satisfactory progress is being made on this fine property. It is situated in Deer Lodge county, and lies 16 miles east of the town of Deer Lodge, within half a mile of the county boundary. The shaft is now down about 250 feet, and they are sinking another 100 feet, when they intend crosscutting to the vein, which will happen, at the present rate of progress, about the 1st of April. During the present month 120 tons of ore from the west level at the 250 were shipped to Anaconda and Great Falls, without sorting, and assays received from this have shown 70 ounces silver and $3 to $3.50 gold. There are 23 men working in the mine.

NEW CARBONATE CAMP.—From a gentleman just in from the new carbonate camp situated at the head of German and French gulches, we learn that there is considerable development going on with the most satisfactory results to the fortunate owners, and he is of the impression that before the end of 1889 it will be one of, if not the greatest carbonate camp ever struck. He anticipates a great influx of visitors as soon as the snow will permit of prospectors. At present there are four mines that are bonanzas, viz.: The Edwards Carbonate Co., the Anaconda Co., the Fisher Co., and the McIntyre Co. There are also some very promising locations on Carbonate hill that will make their owners rich by the judicious use of a grub stake, aided by sufficient muscle to sink a ten-foot shaft. There is a large scope of country south and west of Carbonate Hill that will well repay prospectors to investigate, and he says emphatically that he knows of no camp in this Territory where capital can be placed to better advantage. Being so highly impressed with this idea, he intends returning as early as practicable to test the correctness of his opinions. He speaks flatteringly of the gold lead owned by Doctor Beale and his son Perry.

THE PARNELL, west of the Anaconda, is now down 380 feet. When the depth of 400 feet is reached crosscutting will be begun to reach the continuation of the same lead they had last summer.

OREGON.

THE DOWNIE CLAIMS.—Bedrock *Democrat*, Feb. 23: Mr. Archie Downie expects to commence his placer operations at Sumpter within the next two weeks. His claims are equipped with all the latest improved appliances for scientific working, and should the season be at all favorable he will have a successful run. He has just purchased upward of 600 feet of hydraulic pipe from Mr. L. W. Nelson, and the same will be hauled to his mine at once. In addition to this he has already 2000 feet of pipe in position at the mine. Last fall he completed a new ditch to bring in a water supply from a lake high up in the mountains, and he will commence this season's work under more favorable auspices than ever.

CRACKER CREEK.—Bedrock *Democrat*, Feb. 28: Messrs. Ed Hardy, Joseph Murphy, J. W. Virtue and A. McKinnie returned last Sunday afternoon from Cracker Creek, where they inspected the mines of that section and completed other business matters in anticipation of the boom that will soon strike that region. They were all highly elated over the prospects and are confident of there being a great future in store for the mines of Baker county.

UTAH.

STRIKE AT BINGHAM.—Salt Lake *Tribune*, Feb. 23: A big strike is reported in the Galena mine at Bingham. On sinking the shaft below the base ores, seven and eight feet of rich ores were struck, and the owners are in clover.

ANOTHER BIG STRIKE IN PARK CITY.—The city was all astir to-day at the announcement that a rich and extensive strike had been made in the Creole claim. On investigation the report was found to be authentic, and if present appearances are not deceiving, the Creole will soon add its name to the heavy ore-producers of the camp. The claim is owned by David F. Condon, but was leased and bonded a short time ago to D. S. Deacy and E. N. Jenkins, under whose working the strike was made. For three or four years there have been shipments of ore from the Creole, but in small quantities. The present strike is in the old workings, and the ore body is over one foot wide and dipping downward.

MINES ABOUT OPHIR.—The Jim Fisk will soon have its ten-stamp mill running, as it is nearing completion. Only the machinery to put in position; and in another month or six weeks we will hear the ever-welcome whistle. Its tramway from mine to mill is being pushed with all haste so as to have it ready as soon as the mill is ready to begin crushing. The 5-20 mine owned by Appleby and Henefer still holds its own, and is now included among the paying properties of the camp. On Lion Hill Brim Bros. are working three chimneys and are taking out some splendid ore. Monarch No. 1 is in about 600 feet and showing 900-ounce ore. The Lizzie tunnel is in about 500 feet with a shaft of 50 feet, thence to face of tunnel 300 feet and showing 250-ounce ore. The Toalman chimney has a shaft down 95 feet which cuts the ore pipe, which is lying flat. This chimney just at present is in a pinch; but the ore matter is about 3 feet thick. Ore from this property goes from 50 to 200 ounces in silver, 20 to 40 per cent lead, and $8 to $10 in gold. These three chimneys have yielded in the last five years $90,000. The Gold Note mine, owned by Brim Bros., is looking fair to be one more of the bonanzas of the camp.

THE COPPER COMPANY.—Cor. Salt Lake *Tribune*, Feb. 24: The copper smelter at or near Frisco is shut down and all hands discharged. The prospects for resumption are good at some future day; there are many rumors, but the outlook is good so far as the ores are concerned. Under a consolidated management, this property can be made to pay a good dividend. A plant for reduction should be erected at Frisco or Milford. The miners have not received their pay yet in full, but Charles Lammersdorf is now cashing their time for five per cent discount. This is much better than many a poor miner has had to take on the Pacific Coast. I think a new management, a new and a practical reformation and consolidation of the Cactus and Comet companies will be the best way out of the dilemma.

MECHANICAL PROGRESS.

A Bicycle Locomotive.

A new bicycle engine has been running on a special track in an Eastern city, according to the Boston *Herald's* report, in a manner that astonishes all beholders and promises, it is said, to "revolutionize" the present systems of travel, and prove itself a great economizer in the cost of operating engines. The reporter's interview with the inventor is quite florid, but possibly not exaggerated in the revelation he received. The inventor was asked to give some details in regard to the invention. He answered substantially as follows:

"With one-quarter steam and a consumption of 50 pounds of coal per hour, the 20-ton engine was moved back and forth a majority of times with the steam shut up, working by expansion. So accurately balanced was it that the wheels, all of them within half an inch of the guiding beam, frequently stood entirely still. There was no swaying whatever from side to side; the smoothness, stillness, ease and grace of motion was all that could be desired. It was simply the bicycle running on smooth steel and pushed by steam to which 500-man power could be applied by increasing the furnace fires. This machine has a wheel eight feet in diameter and two engines, each 12x14 stroke. From 550 to 600 revolutions or turns, equivalent to 150 miles per hour, are its piston speed and valve action. It is expected to take four cars, each seating 88 passengers, 100 miles per hour if necessary. The weight of these cars is 28 tons, or seven tons each. It would require 10 palace cars, weighing 400 tons, or five passenger cars, weighing about half as much, to convey the same number of passengers we carry with 28 tons."

"Then there must be a tremendous saving?"

"Not only do we save five-fold in the weight of the train, but the friction of the bicycle spindle wheels is less than one-half of the ordinary double-track train. A saving of ten to one in the power required permits the attainment of an average speed of 100 miles per hour, or the carrying of freight and passengers at the present rate of speed, with from five to ten fold saving in power required. The cost of equipment and of wear and tear will be proportionately reduced; each single-track railway, by this single-rail system, becomes a double track, without the purchase of any new land, grading, bridging or tunneling. The only added expense is the upper skeleton frame with guiding beams, 16 feet above the track, which will cost, when made of wood, from $1500 to $3000 per mile, or, if made of steel, about $3000, exclusive of the double-length ties to which the arching steel is fastened. The average cost of tracking roads is about $30,000 per mile. By this system one-tenth of that sum with wood, or one-ninth of that sum with steel, gives ample allowance for every contingent expense. No steel rails are used overhead, only wooden guiding beams, and the wheels scarcely ever touch them, going straight."

"How about safety?" "The safety is nearly absolute, if very high rates of speed are not desired. There is no wedging or side strain, or oscillation, with the bicycle train, which is grooved both above and below and cannot leave its track, and when made of steel, 14 feet deep, it can neither break nor burn, and with additional safety wheels wrecking is practically impossible. The overhead structure carries the wires, with which an engineer can converse in a fog with a train 50 miles away, or with the station-master while he is moving 100 miles per hour."

A company has been formed in New York, with a capital of $5,000,000, to operate these engines in the interest of some of the business men and capitalists in that city. The inventor claims that, for passenger trains, an average of 100 miles per hour will be easily obtainable, and the first unfinished bicycle engine in its exhibition proved it.

The possibilities of the new bicycle engine many scientific men believe will never be surpassed in transportation, either in simplicity, ease, economy or speed, and that the bicycle system of steam, or more likely electric, transportation will be used until earth ceases to be inhabited. Everybody congratulates the inventor upon the success now seemingly assured after ten years of thoughtful preparation and experiment, which he believes is to prove a lasting benefit to mankind, and while leaving to his family an ample fortune, will leave him a great name as one of the world's benefactors.—*Chicago Journal of Commerce.*

THE PARADOXES OF SCIENCE.—The water, says a writer in *Blackwood's Magazine*, which drowns us, a fluent stream, can be walked upon as ice. The bullet which, when fired from a musket, carries death, will be harmless if ground to dust before being fired. The crystallized part of the oil of roses—so grateful in its fragrance, a solid at ordinary temperatures, though readily volatile—is a compound substance containing exactly the same elements, and in exactly the same proportions, as the gas with which we light our streets. The tea which we daily drink with benefit and pleasure produces palpitations, nervous tremblings and even paralysis, if taken in excess; yet the peculiar organic agent called theine, to which tea owes its qualities, may be taken by itself (as theine, not as tea) without any appreciable effect. The water which will allay our burning thirst augments it when congealed into snow; so that it is stated by explorers of the Arctic regions that the natives "prefer enduring the utmost extremity of thirst rather than attempt to remove it by eating snow." Yet if the snow be melted it becomes drinkable water. Nevertheless, although if melted before entering the mouth it assuages thirst like other water, when melted in the mouth it has the opposite effect. To render this paradox more striking, we have only to remember that ice, which melts more slowly in the mouth, is very efficient in allaying thirst.

A New Copper Industry.

The English correspondent of the *American Manufacturer* notes a new copper industry in Great Britain:

A revolution in the copper industry is promised in the prospectus of a new company formed with a capital of £200,000 to acquire and work the British patents of the discovery of Messrs. F. E. Elmore and A. S. Elmore for manufacturing copper articles direct from rough copper bars. By this process copper is electrically deposited from the rough bars upon a revolving mandrel or mold, over the face of which a burnisher moves automatically and so condenses the copper particles as they are deposited. Thus the material is not only rendered dense, silky, fibrous, and cohesive, possessing at present unobtainable strength, ductility, and uniformity, but at the same time articles can be produced at low cost hitherto unknown.

The advantages of this new process, as certified to by authorities, including Mr. W. Parker (chief engineer surveyor to Lloyd's register), and other equally eminent persons in their profession, may be summarized thus: 1. In the manufacture of tubes and similar articles all drawing down and brazing is entirely dispensed with. 2. There is practically no limit to the diameter of seamless pipes and other articles that can be produced, while by present processes these are strictly limited as to size. 3. Many copper articles, especially large tubes, vats, cylinders, and the like, can be produced direct from rough copper far cheaper than by any other process. 4. The electrical conductivity of the annealed copper is greater by 4½ per cent than that of the best commercial copper. 5. The products of the process have the advantages of quality already noticed; and 6. The copper can be varied in tensile strength and ductility according to the requirements. These are practically the entire claims of the inventors, which they support with a considerable quantity of expert evidence. The inventors anticipate from their process such results for copper "as Bessemer's process has achieved for iron and steel."

Works in Sheffield have been secured by the company, and it is estimated that the machinery can be completed and the factory commence work in about three months. Meanwhile, negotiations are pending with the well known firm of copper smelters and manufacturers, Thos. Bolton & Sons of Oakamoor, Widnes, and Birmingham, to adapt Messrs. Elmore's invention to their electrical plant, with a view to a permanent arrangement for its use by them on a royalty. From its own works a probable return of 70 per cent is modestly set down by the promoters of the company.

A NOVEL LOCOMOTIVE.—An application for a patent has been filed by a New York civil engineer for a new locomotive and tender designed for making the fastest time which has ever been made in this or any other country. The boiler is rectangular in shape, having a large and permanent area of evaporating surface, the pressure to be carried being 210 pounds per inch, which is but one-third of the bursting pressure at its weakest point. The cylinders are in the rear of instead of between the truck wheels, and the fire-box is supported between the center of gravity of the driving wheels. All the combination of parts are in exact harmony, and it is intended to easily make the time of 60 miles an hour with 10 coaches, and can, it is claimed, without violent strain be brought to 85 miles an hour with the same load. This gain in performance over the present machine is achieved by a mathematical construction with reference to the distance between rail centers upon which it is supported, and is the first application made which has embraced and specified every portion of a locomotive and tender constructed mathematically with reference to the limits within which they must be confined and supported. As a result of exact proportion, with reference to such base, the cost of maintenance will be greatly below the general average of present construction.

SHARPENING KNIVES.—A dealer in cutlery expresses the opinion that not one man in 50 knows how to sharpen a pocket-knife. "A razor," he says, "must be laid flat on the hone, being hollow-ground and requiring a fine edge. But a pocket-knife requires a stiff edge, and the moment you lay it flat on a stone, so as to touch the polished side, you ruin the edge. The blade must be held at an angle of 20 or 25 degrees, and have an edge similar to a chisel. This is technically called the 'cannel,' and is marked on all new knives by a fine white line which does not remove or touch the polished surface. Knives improperly whetted are often condemned as too hard or too soft without reason."

SCIENTIFIC PROGRESS.

Substances Liable to Spontaneous Combustion.

Cottonseed oil will take fire even when mixed with 25 per cent of petroleum oil, but ten per cent of mineral oil mixed with ten per cent of animal or vegetable oil will go far to prevent combustion.

Olive oil is combustible, and mixed with rags, hay, or sawdust, will produce spontaneous combustion.

Coal dust, flour dust, starch, flour (especially rye flour) are all explosive when combined with certain proportions of air.

New starch is highly explosive in its comminuted state; also sawdust in a very fine state, when confined in a close chute and water directed on it. Sawdust should never be used in oil shops or warehouses to collect drippings or leakages from casks.

Dry vegetable or animal oil inevitably takes fire when saturating cotton waste at 180° F. Spontaneous combustion occurs most quickly when the cotton is soaked with its own weight of oil. The addition of forty per cent of mineral oil (density .890) of great viscosity, and emitting no inflammable vapors, even in contact with an ignited body at any point below 338° F., is sufficient to prevent spontaneous combustion, and the addition of 20 per cent of the same mineral oil doubles the time necessary to produce spontaneous combustion.

Patent driers from leakage into sawdust, etc., oily waste of any kind, or waste cloths of silk or cotton, saturated with oil, varnish or turpentine.

Greasy rags from butter, and greasy ham bags.

Bituminous coal in large heaps, refuse heaps of pit coal, hastened by wet, and especially when pyrites are present in the coal; the larger the heaps the more liable.

Lampblack, when slightly oily and damp, with linseed oil especially.

Timber, dried by steam pipes, or hot water, or hot-air heating apparatus, owing to fine iron dust being thrown off, in close wood casings or boxings round the pipes, from the mere expansion and contraction of the pipes.—*American Miller.*

An Electric Drill.

I. E. Story is a genius. He has patented an electric drill which promises to almost revolutionize mining as well as tunneling—anything requiring work in hard rock. We had the pleasure of watching the drill last night. It is run by a motor which gets its power from the electricity furnished by one of the large dynamos. The motor itself is about eight inches long and seven in diameter. The armature is about four inches in diameter. The shaft which the armature runs on is hollow, so that water can pass through it and through the diamond drill. The motor works easily on bearers, and as the drill forces itself into the rock is moved along by a screw. At the rear end of the machine a brass tube is put over the hollow shaft and this is connected with the water pipe so that water is let into the drill as may be desired. When the drill is at work in a mine the water is forced into the drill by means of a small rotary pump. This is attached to the end of the revolving shaft. The faster the drill works the faster is the water pumped in. When the drill is quiet no water flows, as it is to come from a barrel or tank or pool at some distance from the drill.

The drill used last night was 1¼ inches in diameter. By the movement of a lever similar to that used in turning on an incandescent light, the electricity is attached and the drill begins to whirl and the water to flow. Full pressure was not put on the drill when we saw it, yet in one minute and one second, exact timing, it had bored a hole an inch and three-quarters deep into the very hardest granite to be found in our hills, and we believe we have the hardest granite in the State in this county. The drill, if crowded, can run 2 and even 2½ inches a minute. Running two inches a minute it can bore, if it were not for the time lost in putting on sections, ten feet an hour. Mr. Story estimates that one of the 400-light incandescent dynamos will run 20 drills easily, each one with a capacity of boring on an average two inches a minute in the hardest kind of rock and more in softer kind.—*Bowlder (Col.) Herald.*

MOTION AT REST.—An exceedingly interesting illustration of the phenomenon of "motion at rest" has recently been exhibited before the Royal Institution, London, the demonstration being so complete that small type placed on a disk, revolving several thousand times a minute, was seen and read with entire distinctness. The accomplishment of this unique result was brought about by means of an electrical arrangement which caused brilliant sparks to illuminate the print at the exact instant only when the type was vertical. But for the buzzing produced by the great velocity of the disk, the words would have been supposed to be entirely at rest. This application of the electricity spark of course gives a ready means of observing any and all changes which may take place in either matter or machinery in rapid motion.

Underground Waters.

Prof. Daubree shows, in an interesting paper on the above subject in the *Popular Science Monthly*, that underground waters are potent agents in the formation of minerals. The following extract will be found instructive:

The mode of formation, or, as Buffon said, the genesis of minerals, is one of the interesting questions of their history. But the problem could not be approached until geologists had furnished precise data on the conditions of their bearing. Satisfactory solutions have recently been obtained in the case of a certain number of mineral species. Synthetic experiment, placing itself in the circumstances that seem to have presided at their formation, has succeeded in reproducing them, with their crystalline forms and all their essential characteristics, and has thus completed the demonstration of their origin. By means of this method of demonstration we have been able to ascertain that many minerals are due to the action of subterranean waters. From the most ancient epochs these waters have circulated through the crust of the earth, where they have left, at a multitude of points, signs revealing the part they have played and the course they have taken even more clearly than contemporary phenomena have done.

The sedimentary beds, formed like the deposits which the sea spreads every day in the bottom of its basin, are often distinguishable from one another, even at first sight, by certain exterior characters. The differences are, for the most part, produced by the action of subterranean waters, as is demonstrated by the animal and vegetable fossils, which were for a long time designated as petrifications, or, rather, by the chemical changes which these fossilized bodies have evidently undergone.

Here shells and corals, showing forms perfectly preserved down to their slightest details, are no longer composed of carbonate of lime, as they certainly were during the life of the animal to which they belonged, but are essentially different substances, quartz having entirely taken the place of the calcium carbonate. There are also other minerals, such as pyrites and sulphate of baryta, which have penetrated and crystallized within the cavities which the bodies of these invertebrates occupied.

A NEW DICTIONARY.—The first volume of the Oxford dictionary has been published. The aim of the work is declared to be "to furnish an adequate account of the meaning, origin and history of English words now in general use, or known to have been in use at any time during the last 700 years. It endeavors (1) to show, with regard to each individual word, when, how, in what shape and with what signification it became English; what development of form and meaning it has since received; which of its uses have, in the course of time, become obsolete, and still survive; what new uses have since arisen, by what processes and when; (2) to illustrate these facts by a series of quotations ranging from the first known occurrence to the latest, or down to the present day, the word being thus made to exhibit its own history and meaning; and (3) to treat the etymology of each word strictly on the basis of historical fact, and in accordance with the methods and results of philological science." The first volume, which deals with the letters A and B only, contains 31,254 words in 1240 pages. In Johnson's dictionary, A and B occupied 127 pages.—*N. Y. Sun.*

NEW USES FOR OXYGEN.—One of the industries now followed in London is that of separating and storing oxygen from the atmosphere. This curious industry has an application in the maturing of spirits and the improvement of beer. This is far from being the only application of pure oxygen, for which the price is good; but it is notable, and no doubt distillers and bonders will give heed to the discovery. It is said that the oxygen, in contact with spirits, accomplishes in a few days what is done by from three to five years by nature. The oxygen gets rid of the fusel oil quickly, and as this is the most injurious property of spirits, the consumer has an interest in the matter as well as the producer. A maturer effect is also produced on beer by admixture with oxygen, and obviously this gas is of high value for the whole tribe of effervescing mineral waters.

A STRANGE PHENOMENON is noticed in connection with the natural gas supply at Montpelier, Ind. Six hours out of every 24 the gas runs down to a minimum and six hours daily it reaches a maximum. While at low ebb the valves are often wide to get a sufficiency, and when at the highest point the smallest turn of the key will supply the demand. The movement is constant with the ocean tides, but whether or not the same influences are the cause is a matter of conjecture.

A NEW PROCESS FOR METAL-PLATING is being introduced, in which the batteries and dynamos are dispensed with and the operator depends upon a double electric composition. In copper-plating cast iron an electric bath is used in place of an acidulated one.

ORGANIC EVOLUTION.—Prof. Geddes calls attention to two tendencies in organic evolution—the vegetable and the reproductive—and asserts that evolution is the result of the universal subordination of the former to the latter.

GOOD HEALTH.

How to Prolong Life.

How to prolong human life is a question of personal interest to every man, and the duty of making an attempt to do so is one that particularly rests with the medical profession. When an individual has attained to full development and sound health—say at 40—the expectancy of life may be 25 or 30 years; for the individuals there are great risks, but with the aggregate of mankind such questions may be calculated with business-like accuracy. There are two great factors which concern the prolongation of a human life—the inheritance and the conditions which make up a life history of the individual. The inheritance of longevity from one or both parents is a powerful factor, and one that carries great weight with life-insurance offices. This is a more important factor than an infancy free of weakness, provided that the infantile ailments be dependent upon temporary conditions of defective nutrition, or conditions incident to the stages of development only. The late Emperor William and many other public men of great age and useful life, illustrate that a feeble youth may be followed by a robust and prolonged life. Even conditions of infantile marasmus may be followed by subsequent good development, as in the case of Sir Isaac Newton.

We now proceed to speak of average people, for "a perfect man" can hardly be said to exist; we shall consider average people, especially as we see them in town life, and the special conditions we desire to note are the habits, diet and the wear of life. There is no doubt as to the importance of the habits of life affecting longevity; temperance in all things, in activity and restraint, in regularity in morning rising and in work, as well as in resting and in sleeping, uniform industry is as conducive to health as is regularity in diet. The acquisition of regularity in habits is largely due to early training, and in this way a wisely directed school discipline probably does much to form a sound and steadily acting nerve system, such as give the man a power of resisting adverse influences and prolonging physical health. From the period of infancy upward a sound and well-knit brain has much to do with the permanence of a healthy constitution. The relation of diet to longevity has often been discussed; we can only say here that the diet should be adapted, in quality and in kind, to the work of the individual; while such articles as alcohol, tobacco and tea, if used at all, should be employed in moderation by those who wish for a stable constitution and prolonged life.

Passing over such important consideration, as being familiar to most members of the profession, we come to the great question of the causes of wear in life—the outcome of the frictions of life which all must meet with, more or less. The various factors at work, especially in a town life, make impressions on the brain which lead to fatigue and premature wear. The strong-brained individual may not be hurt thereby; the weaker man is exhausted by such constant impressions from without, and a second generation under such influences is likely to suffer, through loss of tone and vitality, in cell structures rather than in actual stature and measurement. City life naturally produces a rapid and unceasing series of impressions and calls for constant exertion. The laws of sanitation and cerebral hygiene should then be carefully studied. It is very desirable to have what quietness is possible during brain work, and the necessity for proper ventilation as a means of maintaining mental energy is well known. It might lessen brain wear in many offices if electric lighting was substituted for gas illumination. Good digestion is essential to continued work with good lasting power. Late rising and a still more hurried luncheon and rush back to work, followed at the conclusion of the day by a heavy meal when the man is wearied, often tend to exhaustion, as much as the unavoidable pressure of business. A most rational refreshment after heavy brain work is to partake of light refreshments and then rest for half an hour before dinner; thus the power of digestion and social enjoyment are restored to the man.

Probably the chief means of preparing a man to withstand the wear of business life is by a careful training, both physical and mental, before he enters upon the struggle and wear of business. One means of increasing the chances of longevity is by training the child wisely. Many a premature breakdown of health is due to that want of preliminary exercise which would not be neglected by the athlete without disaster.—*British Medical Journal.*

A Convenient and Wholesome Privy.

Referring to the prevalence of typhoid fever and diphtheria, and the danger to health and life from vaults which are improperly placed or constructed, a correspondent of the *Country Gentleman* tells how he manages to avoid such a privy as commonly exists at farmhouses. He has provided an arrangement that answers all purposes of convenience, and can be cleaned out twice a year and used as manure, leaving no permanent deposit in a pit that can infect earth or air or cause disease. He says:

The common small building, placed at a short distance from the dwelling, or connected directly with it, stands where the ground is slightly descending from its rear, so that access may be had to the vault once or twice a year by lifting up a closely fitting swing door, which is partly hid by shrubbery. In the common room over this, containing the seats, is a box or barrel containing muck, ashes or road dust, with a long-handled dipper. A conspicuous placard is placed in front of the visitor with the words "Throw down a dipper of ashes every time, and shut down the cover." Properly instructed, every visitor will do it; but it is well for the owner to examine occasionally to see if enough is thrown down to absorb everything of a liquid nature. The vault must, of course, be well drained, and be so placed that no surface water can enter it. Then, with the case just mentioned, no drainage can pass from it. The whole expense, besides the building, is the box or barrel, standing in one corner, and the dipper, both not costing more than $1, unless the owner procures a smooth, handsomely painted barrel or box at greater expense. From this box a dipperful may be used in two or three seconds, and with about as little labor as to pull the button. The machinery is as simple as it can be, and can never get out of order.

The dust and ashes can be mixed to advantage, and if enough is used to absorb everything, and the place is kept dry, there will be nothing offensive to handle in hauling away and cleaning the place. No bad odors exist, and the privy is a much nicer place than ordinary. This is even better than a water closet.

This subject is of great importance and many doctors' bills and many lives would be saved if such means were used to prevent infection and disease.

MEDICINE FOR THE POOR.—A number of prominent physicians of this city have organized themselves into a society under the name of the San Francisco Polyclinic, with headquarters at 124 Ellis St. It is the intention of the society to furnish medical advice and treatment to the poor free of charge. Certain physicians have been detailed for particular classes of treatment. The hours to be given will be announced at an early day. The institution will also partake of the nature of a post-graduate school for actual practitioners, but no students will be admitted.

WARM WATER.—A pint of warm water taken on an empty stomach in the morning is the safest and surest of all remedies for habitual constipation. It dissolves the fecal matter and stimulates peristaltic action, thereby giving a normal action without pain. If the tongue is coated, squeeze a lemon into the water and drink without sweetening.

THE EYESIGHT.—It is well known that practice in looking at distant objects improves the eyesight. In the test for color blindness among the engineers of the New Jersey Central road, it was found that the oldest man in the service had the best sight for long-distance purposes and was better able to distinguish the various shades and colors.

USEFUL INFORMATION.

WHY CANNING PRESERVES FRUIT.—Many people have never given this matter a thought, while others have often wondered why such was the case, and there let the matter rest. Therefore, it is interesting to many, and they will be glad to know why sealing fruit up in air-tight cans or bottles keeps it from spoiling. Germs of ferments and molds are everywhere present in the air. So long as fruits are alive and growing in a healthy state, they are mostly proof against decomposing agents, but as soon as they lose their vitality through changed conditions, with but very few exceptions they soon and easily spoil. When preserved fruit is put into cans or bottles hot and perfectly sealed while in that condition, the germs of decay present in the fruit and can are killed by the heat, and the sealing excludes the germs on the outside from coming into contact with the fruit.

KEEPING PLANTS THROUGH WINTER WITHOUT ARTIFICIAL HEAT.—A new principle for keeping plants through the winter without artificial heat was recently shown at Regent's Park, London, with the plants grown in them last winter. The essence of the invention is that all light and heat shall previously pass through a shallow layer of water. The water is found to exercise great control over temperature, protecting plants entirely from frost in winter, and from excessive direct heat in summer. The application involves no difficulty. In the case of a garden frame, a sliding "water light" about three inches deep is made to fit over the frame containing the plants; the only difference from a glass light being that it holds water and is always placed in a flat position. The depth of water generally kept in the tank is about two inches in winter and summer, and half the depth in spring and autumn.

HOW TO FORETELL A STORM.—Says a weather observer: "When you wish to know what the weather is going to be, go out and select the smallest cloud you see. Keep your eye on it, and if it decreases and disappears, it shows a state of the air that is sure to be followed by fine weather; but if it increases, take your overcoat with you if you are going away from home, for falling weather is not far off." The reason is this: When the air is becoming charged with electricity, you will see every cloud attracting all lesser ones toward it until it gathers into a shower, and, on the contrary, when the fluid is passing off, or diffusing itself, then a large cloud will be seen breaking into pieces and dissolving.

MANUFACTURE OF GIRDERS.—The substitution of steel for iron in girder manufacture appears to be making steady progress. The *Moniteur des Interets Materiels* states that for the large new warehouses in course of erection at Buenos Ayres, steel girders are specified, and that as these cannot be advantageously obtained in Belgium, the contractors, Halot & Co., Louvain, have had to place the order with the Rothe Erde Works, in Germany, a concern which makes a specialty of this kind of work. As the order is for 5000 tons, the Belgian iron-girder rollers are asking themselves to what extent steel girders are likely to replace iron in the future, and how far their present practical monopoly of the export business in large rolled girders is threatened by this preference for steel. The *Moniteur* draws comfort from the reflection that, while for the nine months ending Sept. 30th, the export of steel from Belgium was only 80,000 tons, the shipments of manufactured iron reached 210,000.

AN INGENIOUS DEVICE for controlling excitable horses has been invented, says the *Indiana Farmer*. It is attached to the brow band of the bridle, and a light but firm cord runs through loops along the reins to the hand piece. In case of fright pull the cord, and instantly the horse is blindfolded. This diverts his attention from the object of fright and puts him into another train of thought. Let go the cord and the double spring instantly withdraws the blinds from the eyes and rolls them out of sight.

FIXING INDIAN INK.—Indian ink, as most of our readers know, is composed of the finest ivory-black and a gelatine size, and is excellent for plans and drawings until any color "wash"—or even a little dampness—comes near the lines, when they then either "blur" or "run" all together. This may be prevented by dissolving in the water used for rubbing up the ink about eight grains of bichromate of potassium, or 6½ of the corresponding ammonium salt per fluid ounce.

STONE-BREAKING.—It is well known that a stone, however large, may be broken by striking a sufficient number of blows with a hammer along the line where it is desired to break the stone. In this process the force of the blow is expended in gradually weakening the cohesion of the particles in a line following the direction of the blows. This weakening is increased by each successive blow until finally rupture occurs.

ANILINE COLOR FACTORIES.—It is said that there are four manufactories of aniline colors in the United States. Up to the Tariff revision of 1863, the business was uniformly profitable; but since that revision the protection has been insufficient, and the business has languished. It is barely kept alive, because of their inability to compete with foreign cheap labor. The difference in cost between Europe and America is as 100 to 139.

WATER PRESSURE.—A body of water, such as is in a canal lock, tank or cistern, has a static pressure equal to .43 of a pound per square inch for each foot in depth. Thus, at the bottom of a depth of ten feet, the pressure would be four and thirty hundredths pounds per square inch; but the average pressure against the sides would be half that, or two and fifteen hundreths pounds, as there is no pressure at the top.

SCENT PENCILS, composed of solidified perfume, are a novelty. They are fitted in silver holders, have a tiny ring attached to them for fastening the watch-chain or chatelaine, and when rubbed on the hands or any part of the dress emit a delicate odor.

KEROSENE OIL AND SHARKS.—It is said that a Key West fisherman rubs his body with kerosene oil and swims among the sharks in safety. They don't want to get any nearer to him than you do to a man who has been eating last year's onions.

THE COST OF BREAD.—The distribution of bread after it is baked now costs the average workman in a city as much as it does to grow the wheat, mill it, barrel it, move it 1500 miles and convert it into bread, all put together.—*Forum.*

THE SWEAR.—General Lew Wallace says that he has seen a thousand men receive wounds, and he never knew one to swear when struck. It is like falling off a wharf. The swear comes after the shock of surprise.

AN ELECTRIC HAND-SAW is the latest invention for carpenters. It works like any ordinary saw, the electricity being applied only in the process of setting and sharpening.

COLLIERIES IN INDIA.—One hundred and five collieries are open in India, says London *Truth*, and in 1886, 1,400,000 tons of coal were mined.

IT is said that collodion dissolved in alcohol and applied with a soft brush will prevent silver from becoming tarnished.

The Big Pend d'Oreille Discoveries.

Mr. J. L. Johns, a Butte assayer, has just returned from a trip to the new camp being started not far from the Pend d'Oreille lake. In conversation with a reporter of the *Inter-Mountain* Mr. Johns gave some particulars about the new camp and discoveries, which will be read with interest by the Butte public.

How to Reach Chloride.

In order to reach the new discoveries it is necessary to get off the Northern Pacific train at Hope, a station half-way between Thompson Falls and Spokane Falls. This point is on the Pend d'Oreille lake, and from thence a steamer runs straight across the lake to Gray's Landing, a distance of 26 miles. The camp of Chloride City lies about six miles from this landing, at the mouth of three gulches. Though the camp is only three months old, there are already 600 men there and 300 cabins are in course of construction. Lots are selling all the way from $50 to $500, and not a foot of ground remains to be located within several miles of the camp.

The Principal Discovery

Is of course the Webber and one or two neighboring claims which have been bonded to Helena parties for $250,000, an account of which has already been given in the *Inter-Mountain*. There are ten men already at work on the Webber. It is developed by a discovery shaft about 50 feet deep and three tunnels have been started. The upper one is in 35 feet and has struck the ledge. The character of the rock is free-milling in the upper tunnel, though base rock is found in the lower tunnels. Mr. Johns made no assays from the Webber, but was informed that the rock went $75 in silver. The lower tunnel is only in five feet, and the ore found in it is galena.

Other Claims.

On the other side of the Webber hill are located the Denver, Eagle, Mary Ella, Jumbo, and Hidden Treasure, from all of which Mr. Johns made assays, showing silver to be present in considerable quantities. The chief feature of the camp is the immense width of the ledges, the lead matter in some cases being more than 90 feet in width. There are more than 30 locations on the main lode. The camp of Chloride has been started with a tremendous boom, and all the miners seem confident that a great mining district is to be opened up in that vicinity.

Alien Mine-Owners.

At the last session of Congress the Committee on Mines and Mining was instructed to ascertain and report to the Senate the number of aliens, foreign companies and corporations owning or operating mines in the Territories of the United States, together with the length of time they have been so, the amount of capital invested by them in mining operations, the amount of money expended, dividends paid, and the effect of the ownership of mines by aliens, foreign companies and corporations upon the prosperity of the country. The report was made to the Senate last week.

Since the recess of Congress last October, statistics have been gathered from Idaho, Montana, New Mexico, Utah, Washington, Dakota, and Arizona Territories, by which it is shown that the mining ventures and investments of aliens in these localities amount to more than $30,000,000, from which they have received $4,000,000 in dividends.

The report shows that the railroad companies admit that 75 per cent of their freight comes from the miners, and since March, 1887, when the alien land law went into effect, they have experienced considerable loss in their carrying trade. From information received by the committee it appears that, as a rule, the aliens are quiet and well-behaved members of the community.

The report contains a detailed statement of their operations since opening up the mines, and concludes with a unanimous recommendation that the alien land law be so amended as to allow aliens to invest in mineral lands on their own individual responsibility.

Air Compressors.

The Clayton Air-Compressor Works of No. 43 Dey street, New York, report a splendid trade in the particular line of machinery which they manufacture. They have been taxing their works in Brooklyn to their utmost capacity for the past seven months, and are thinking of making extensions to their facilities, as there seems to be no likelihood of a falling off in their orders for some time to come. They have built numbers of air compressors for export to different parts of the globe, besides doing an extensive trade in the Pennsylvania coal regions and the western mining fields in air compressors to supplant steam in running machines underground, or which from necessity must be situated some distance from the boilers. Any mine-owner or operator knows the advantage to be derived from compressed air under these circumstances. Besides this, they have been doing a large trade in a small vertical high-pressure belt air-pump, largely used in connection with the burning of crude petroleum for fuel and by experimenters generally. A complete catalogue of the different styles of air compressors and other machinery manufactured by this well-known house will be mailed free on application to the Clayton Air-Compressor Works, No. 43 Dey St., New York.

TABLE OF CONTENTS.

EDITORIALS.—British Columbia Mines; Pacific Coast Relief Chart; The "Mining and Scientific Press," 161. Passing Events; The Lower California Gold Excitement; United States Patents; Lithology of Wall Rocks, 168. Inauguration of President Harrison, 169.

ILLUSTRATIONS.—Orographic Map of the Pacific States and Territories, 161. Benjamin Harrison, 23d President of the United States, 169.

CORRESPONDENCE.—Central Idaho; Bad Mining Laws; Grub Gulch and Potter Ridge Mining District, 162.

MISCELLANEOUS.—Yield of Comstock Mines; Photographic Processes; Liability of Mining Directors, 162. Astronomical Affairs; The Geodetic Survey; Gold and Silver; Boxing and Firing Stumps; In Chinatown, 163. The Big Pond d'Oreille Discoveries; Alien Mine Owners; Air Compressors, 167.

MECHANICAL PROGRESS.—A Bicycle Locomotive; The Paradoxes of Science; A New Copper Industry; A Novel Locomotive; Sharpening Knives, 166.

SCIENTIFIC PROGRESS.—Substances Liable to Spontaneous Combustion; An Electric Drill; Motion at Rest; Underground Waters; A New Dictionary; New Uses for Oxygen; Organic Evolution, 166.

GOOD HEALTH.—How to Prolong Life; A Convenient and Wholesome Privy; Medicine for the Poor; Warm Water; The Eyesight, 167.

USEFUL INFORMATION.—Why Canning Preserves Fruit; Keeping Plants Through Winter Without Artificial Heat; How to Foretell a Storm; Manufacture of Girders; Fixing Indian Ink; Stone Breaking; Aniline Color Factories; Water Pressure; Kerosene Oil and Sharks; The Cost of Bread; The Swear; An Electric Hand Saw; Collieries in India, 167.

MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 164-65.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 176.

Business Announcements.

Passing Events.

The inauguration of Benjamin Harrison, the 23d President of the United States, took place on Monday with appropriate ceremonies. The mining community will now be anxious to see what the new administration will do for the silver interests.

The adjournment of Congress left the Alien bill without being acted on. It is unfortunate for the Territories that this important amendment allowing foreigners to purchase mines in the Territories did not pass.

The signing of the Territorial bill admitting as States North and South Dakota, Montana and Washington, will be of great advantage to those regions naturally. From a mining point of view, it will free them from the operations of the existing Alien Land law.

Hundreds of people are crossing the Mexican border to the new mines in Lower California. Fully 2000 people are there already and 500 are on the way from San Diego. The steamers to Ensenada are crowded. Some gold-dust is being sent back, and most sensational reports about the richness of the fields are being circulated.

There is quite an excitement in the copper market, owing to fears of a collapse of the French syndicate. Prices have fallen and there is an immense stock on hand, while production is increasing. The operations of the syndicate, while they have increased the prices to consumers, have largely benefited the copper-mining industry in this country.

The Lower California Gold Excitement.

One of those periodical "excitements" over the finding of gold on the peninsula of Lower California is now raging, this one being possibly more intense than its predecessors. San Diego and other towns in that region are being depopulated of their laborers by the rush to the mines. Stories about $15 to $100 a day to the man are being circulated, and some are told about men getting out $1000 to $1500 in two days. Ensenada is deserted; many men are going from Los Angeles, and numbers have left San Francisco also for the new gold-fields. All the peninsula towns are deserted. At Tia Juana, near the Mexican border, several hundred people are gathered on the way into Mexico. All the laborers on the Cuyamaca railroad have quit work, and the waiters in the San Diego hotels have gone also.

Some one who is styled Prof. Anthony, or Mineralogist Anthony, telegraphs that the Santa Clara gold-fields are the richest in the history of the Pacific Coast, but we should prefer the opinion of some good practical miners on the subject, especially as the "Professor" says the find surpasses in wealth the discoveries in California in 1849.

The placer strip is said to extend 12 miles by 8, and the gold is in coarse nuggets. Quartz is reported also as having been found. Gold-dust is being brought into San Diego for sale, but not in such quantities as to bear out the statement of the mines being richer than those of '49. The $6000 or $7000 has, however, caused great excitement, coupled as it is with the highly colored reports.

Those going overland from San Diego take out "clearance papers." The duty on a horse is $40; on a wagon, 10 cents per pound; on harness, 75 cents a pound; on provisions, 50 to 90 cents per pound; on tents, 10 cents per pound. The clearance papers cost $10. The Mexican Consul must certify to the correctness of the papers. Picks, pans, shovels, drills, fuel, powder, etc., pay no duty. One is also entitled to bedding, one or two firearms, and 100 cartridges, two pounds chewing tobacco, 99 cigars, and personal jewelry and baggage, free, without any papers. If $100 worth or more of provisions appears on one person's papers, he will have to pay the Consul at Tia Juana a $14 fee. If there are others in the party and the supplies are apportioned, this fee may be avoided.

The extreme southern part of the State is in a fever of excitement over this find. This is all very well for men without families and with nothing to do, but those occupied or having families will do best to remain where they are until something more definite is known. The country is a rough one and exceedingly dry. There are several companies down that way having land for sale, and while they may not be spreading these wild stories, such things have been done before. Mines have been worked more or less for generations on the peninsula, and a number of times have placer deposits been discovered. Gold has been found at many points. This spot may be richer than the others, but it is not probable that several thousand people will be accommodated with rich claims. There are many idle men in the southern part of this State who would naturally join a "rush" of this kind, and the departure of such numbers has added to the excitement. Many of these people are from the East of late years, with no experience of "gold excitements," and it would take little to excite them, not being familiar with the methods of interested parties in getting up such things. The character of the news from the mines sent up here reminds old Californians of many similar occurrences during the past 40 years. Eight men out of ten who join these rushes regret the step in the end. Those with time and money at disposal may risk going; very few among those who have gone know anything at all about mining, and we all know how little gold it takes to excite a "tenderfoot" in any mining field.

THE large reduction works at Deadwood, Dakota, were destroyed by fire last week. Loss, $100,000; insured for $35,000.

United States Patents.

The annual report of the Commissioner of Patents shows that the business of the office is constantly increasing. Occasionally there is a slight falling off in the number of applications for patents; but this continues for a time only, when the increase begins again. The examination of an application for a patent involves an examination of the "state of the art" for the entire world. Consequently the mass of matter to be examined by the examiners in each class of art is increased each year by the patents and publications of the year. The field to be investigated grows in extent year by year, increasing the time and labor requisite for a proper examination of an application. It becomes more necessary than ever for inventors to employ only skilled and experienced agents in preparing and presenting their applications, in order to facilitate the examiner's work by presenting the invention in proper form.

The number of applications requiring examination received at the Patent Office last year was 41,351, which, in round numbers, averages 800 per week. The number of patents, certificates of registration of labels and trade-marks during the same period was 21,892, averaging 421 per week, showing a percentage of not quite 50 per centum of rejected applications.

These figures give a pretty good answer to those who maintain that a man can get a patent on anything, and that too many patents are granted. Nearly half the applications were rejected, it seems, so that those who have useful improvements should see that their cases are properly drawn and carefully presented, if a favorable result is to be reached.

The following table shows in a condensed form the history of the patent business of the United States:

NUMBER OF PATENTS AND CERTIFICATES OF REGISTRATION ISSUED DURING EACH CALENDAR YEAR.

YEAR.	Patents.	Designs.	Re-issues.	Total patents.	Trade-marks.	Labels.
1836, July 28...	109	..	..	..	..	..

1880	12,926	515	506	13,947	349	203
1881	15,548	565	471	16,584	836	202
1882	18,136	861	271	19,267	947	304
1883	21,196	1,020	167	22,383	902	906
1884	19,147	1,150	116	20 413	1,021	513
1885	23,331	773	129	24,233	1,067	391
1886	21,797	595	116	22,508	1,029	378
1887	20,429	949	99	21,477	1,133	330
1888	19,585	835	86	20,506	1,059	327

The patent department pays a profit to the Government. The total receipts last year were $1,118,516.10, and expenditures $973,108.78; receipts over expenditures, $145,407.32. This profit has been made for some years, until there is now a balance in the treasury of the U. S. on account of the patent fund of $3,402,898. Notwithstanding this, owing to our system of appropriations, the patent department is cramped for funds. More examiners are wanted and more room is wanted, but Congress pays no attention to the Commissioners' requests. The inventors of the country more than pay for running the office, yet they are put to unnecessary delay and inconvenience in obtaining their patents.

As to the distribution of patents, the following table shows the patents issued to citizens of the United States during the past year, with the ratio of population to each patent granted:

States and Territories.	Patents and designs.	One to every
Alabama	64	19,726
Arizona Territory	10	4 044
Arkansas	69	11,630
California	445	1,943

Lithology of Wall Rocks.

Melville Attwood of this city, who has been for about half a century more or less practically engaged in gold mining and milling, contributes to the annual report of the State Mineralogist a very interesting and useful chapter on "Lithology of Wall Rocks." Colored engravings are given of hanging and foot walls of several prominent mines. The igneous rocks forming the walls of our richest gold mines vary much in composition. The highly crystalline portions, however, appear to have been formed when the liquid mass was cooled down with extreme slowness. There has taken place a great alteration in the constituent minerals of these rocks, owing to the action of chemical forces, which are everywhere at work within the earth's crust, and which have in many cases so changed the appearance of these rocks that specimens taken at different points from the same wall or dike present a different appearance, and their identity may easily escape recognition.

Mr. Attwood in his article gives his ideas of the source or origin of gold found in lodes, veins or deposits; a description of auriferous lodes or deposits of California and their inclosing rocks; a description of the gangues or foreign matter with which the gold is associated; the blanket system of saving gold; and how to make macroscopical examination of the wall-rocks of auriferous fissures.

The article referred to covers many points in a subject to which too little attention has been paid by mining engineers and miners. No doubt had proper comparisons of the rocks been made, many useless expenditures of money would have been saved. An accurate description is given of the rocks in the most prominent producing California gold mines, and sections of the rocks have been prepared and placed in the Museum of the State Mining Bureau. Mr. Attwood's investigations were made in the field, and the mines were examined, so the paper is not merely theoretical, but based on actual observations.

AT the meeting of the California Electrical Society, Monday night, Orion Brooks read a paper on "Fallacies Relating to Galvanic Batteries." A vote of thanks was tendered the essayist for the excellent manner in which he presented the subject, after which a general discussion took place.

ANOTHER heavy blast was made at Telegraph hill last Sunday. Nearly 10,000 pounds of powder were placed in the tunnel. The blast loosened 50,000 tons of rock, which will be used by the contractors in the construction of the seawall.

Inauguration of President Harrison.

We give herewith a portrait of Benjamin Harrison of Indiana, inaugurated on Monday of this week the twenty-third President of the United States. The arrangements for the inauguration were perhaps the most complete and elaborate ever made, and the affair was as impressive and satisfactory as the weather would allow. Those who need a reminder of what March can do at the East in the way of weather may read the following extract from a telegraphed account of the inauguration:

Benjamin Harrison stood with uncovered head in a cold, drizzling rain, with a raw wind blowing in his face, in front of the National Capitol to-day, and took the oath of office as President of the United States. Grover Cleveland stood beside him, with his hat in one hand and an umbrella in the other, which he held over Mr. Harrison. In front of Harrison and Cleveland was the small figure of Chief Justice Fuller in his robes of office and a Testament in his hand. The rain fell on the silver hair of the Chief Justice, which the cold March wind dishevelled. This scene was witnessed by a drenched and shivering crowd, who crowded in front of the portico of the Capitol, and had waited in the blustering wind to see one administration go out and another go in.

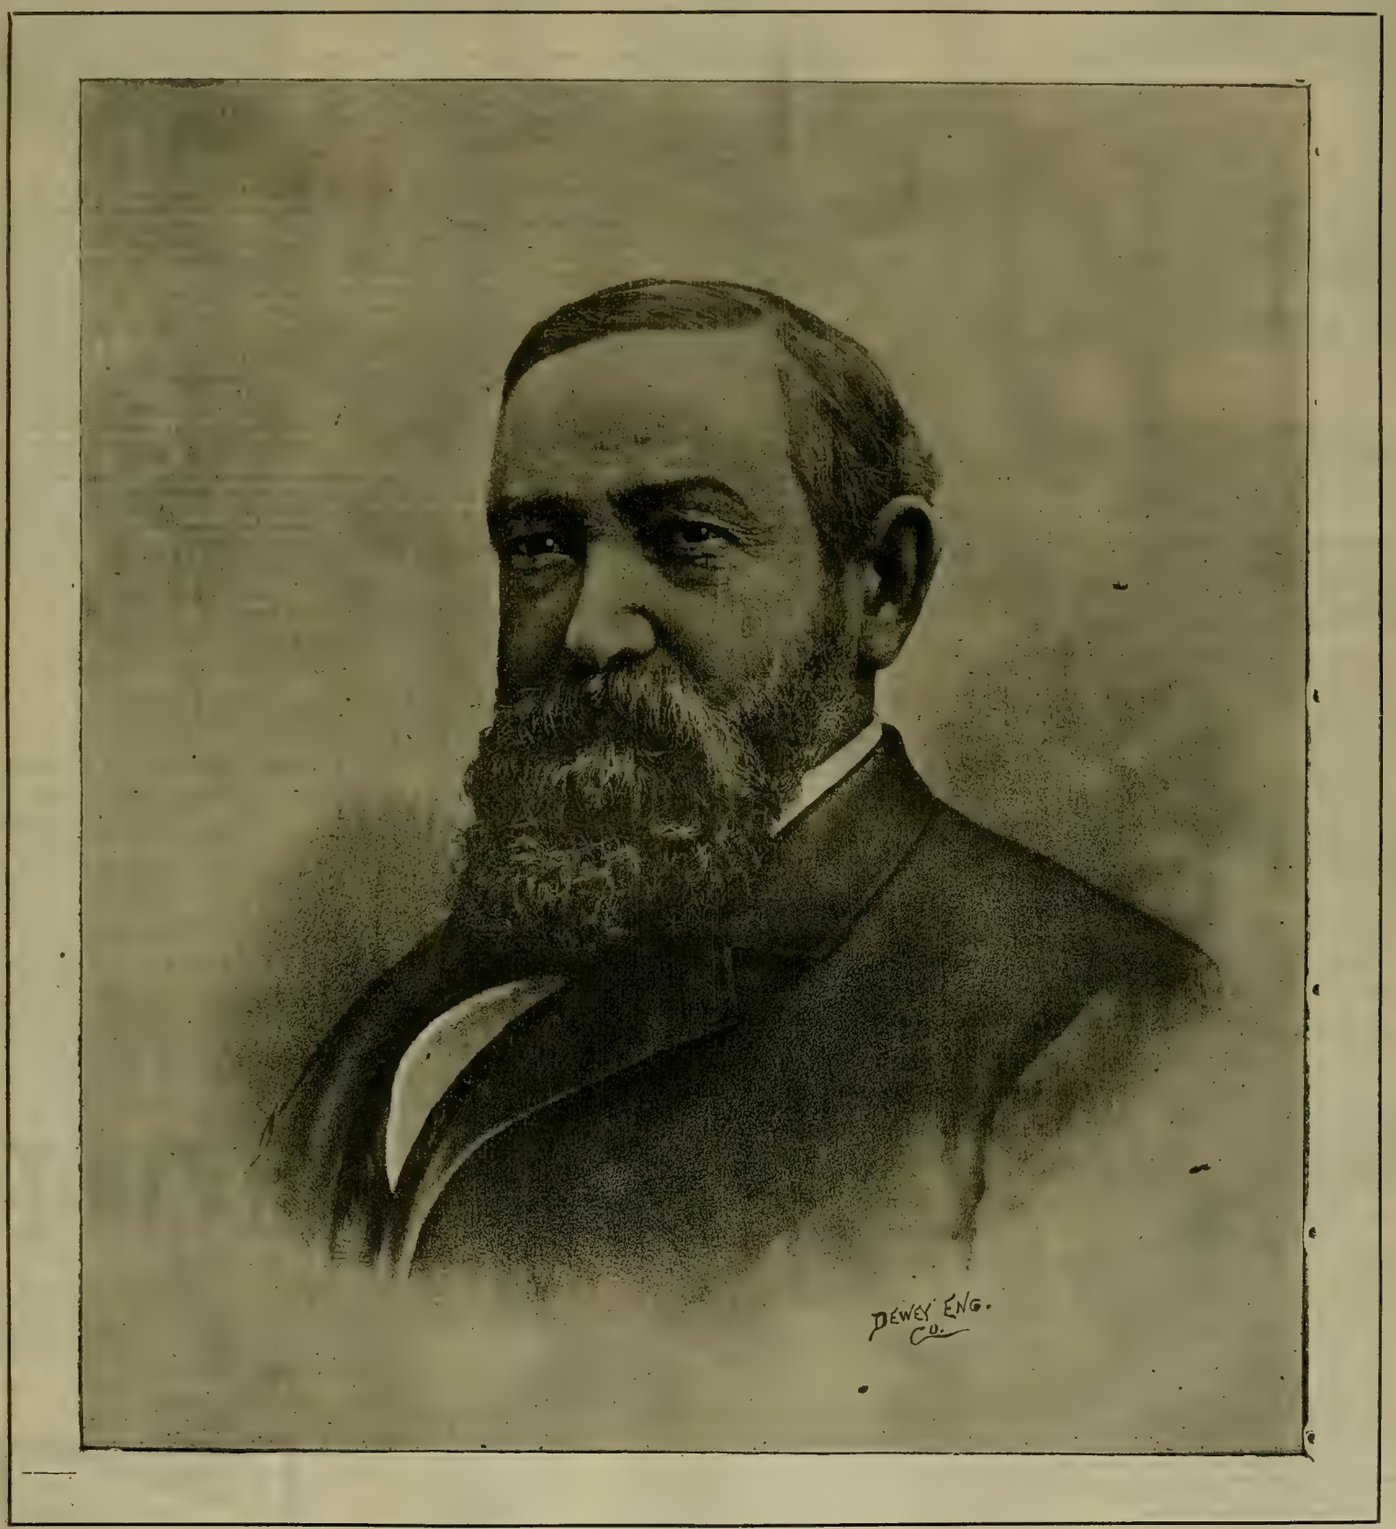
And yet the inauguration was successfully accomplished. The new President read his inaugural address, a paper with many excellent points, and the manifestation of joy, which took form in torchlight parades and a grand inaugural ball, was not dampened, in spirits at least, by the unfortunate weather.

Vice-President Morton took his oath of office and assumed the presidency of the Senate. Thus the new administration begins its labors.

Benjamin Harrison was born at North Bend, Hamilton county, Ohio, August 20, 1833, and is therefore in his 56th year. His father was John Scott Harrison, who served his district two terms in Congress. His grandfather was that famous leader and general, who, after a life of brilliant and distinguished service in the forum and the field, was elected President of the United States, after the most exciting campaign of 1840. His great-grandfather was one of the heroes of the Revolution, Governor of Virginia, and a signer of the Declaration of Independence. One of his ancestors was a general of the Commonwealth of England, before Cromwell's usurpation, and whose unflinching Republicanism cost him his life in the early days of the Restoration. His immediate descendants came to America and founded the family in this country.

Benjamin Harrison received a classical education, and is a graduate of Miami University, Oxford. Immediately after graduation, he commenced the study of law at Cincinnati, Ohio. In 1853 he was married, and in 1854 he established himself at Indianapolis, his present home. On the breaking out of the Rebellion he left home, a successful practice, and all that makes life pleasant, in response to his country's call for her defense. The same diligent application that contributed to his success in peace, enabled him to succeed in war, and the proclamation of peace found him wearing the stars of a general. In 1881 he was elected to the United States Senate, serving out his full term. In 1884 he was prominently canvassed as a Presidential candidate. The memorable convention of 1888, resulting in his securing the nomination, is still fresh in the minds of our readers, and the smoke of the political conflict which ended in his election has only just cleared away.

Those who know him best give assurance that in Benjamin Harrison the country will have a wise, conservative and eminently safe President.



BENJAMIN HARRISON, TWENTY-THIRD PRESIDENT OF THE UNITED STATES.

Coast Industrial Notes.

THE best timber for ships' spars to be found in the world comes from Puget sound.

IN the new California theater there will be used a very large quantity of red sandstone from Arizona mines.

LAST week one-quarter of the employes in the railroad yards at West Oakland were discharged, as a measure of economy.

D. HENSHAW WARD has resigned as General Manager of the Judson Manufacturing Company, and C. B. Morgan, heretofore secretary, has been elected to fill the vacancy.

M. E. HITCHINGS, the principal of a Saginaw (Mich.) syndicate of lumbermen, is in San Francisco preparing for an inspection of the available lumber properties of the coast.

THE Tillamook *Headlight* says: Work on the light-house has commenced, with Mr. Harry Rogers as foreman. At present there will be employed 25 or 30 men, and as soon as the boarding and lodging house is up this number will be increased.

G. W. GORRILL of Oakland has been authorized to make negotiations for a tract of land about ten acres in extent, fronting upon the bay and convenient to a railroad, for a site for a great factory. Mr. Gorrill will seek an available site in Oakland.

THE Watsonville *Pajaronian* says: Something less than 1000 acres of land have been contracted for beets next season, but this acreage includes much of the best land of the valley, and will probably produce more tons of beets than were crushed at the factory last year.

THE elevator system of handling wheat has had only a small trial on this coast. A Minneapolis firm of wheat-buyers thinks that this means of storage can be used to advantage in Washington Territory, and will erect some large elevators near Tacoma in the spring.

MERCURY extracted from cinnabar ore mined in California is most highly prized by the manufacturers of thermometers. Making high-register thermometers has become a business by itself, and considerable art and ingenuity are required to make a success of these valuable instruments.

R. I. PRAY of Towles, Placer Co., says large quantities of lumber are shipped daily. The big reservoir at Lake Valley has now a capacity of 100,000 inches, but contains at present only 40,000. The locomotives and lumber cars have been repaired and ready for use. The pulp-mill has not been started yet.

AT the annual meeting of the Lumber Surveyors' Association, the following officers were elected for the ensuing year: H. Fisher, Pres; J. P. Haines, V. P.; J. F. Clough, Sec.; G. W. Adams, Treas.; Trustees—C. Lyman, R. Pennell and G. W. Adams. Executive Committee—G. A. Morse, A. M. Cook, G. Benson, N. F. Phillips and R. C. Markel.

THE Secretary of the Treasury has awarded contracts for the erection of a life-saving station at Fort Point, California, to James H. Coster of Baltimore for $11,100; for the erection of a station at Point Reyes to John E. Hammond & Co. of San Francisco, for $8195; for alterations and repairs of the Humboldt-bay station to W. H. Mills of Eureka, for $3675.

WORKMEN have commenced the erection of the watch factory at Otay, about ten miles from San Diego. A side-track has already been put down. The main building will be 38x100 feet, three stories, and of brick, with boiler, engine and other rooms attached. The superintendent of the factory, P. H. Wheeler, says 20 watchmakers and their families are en route from the East.

UNDER the new administration the Merced Woolen-Mills will be enlarged by a 50 foot addition. The manufacturing capacity of the mills is to be increased one-fourth by the addition of new machinery. The present annual product of the mills has a selling cash value of $300,000. Hereafter the mill managers expect to manufacture flannel, cassimere and blankets to the extent of $400,000 per annum.

THE Port Townsend *Call* says: Captain J. J. Smith and others of San Francisco have contracted with Hall, the ship builder of Port Blakely, to have built a four-masted schooner of the following dimensions: Length of keel, 178 feet 2 inches; beam, 38 feet; depth of hold, 14 feet. She will have a carrying capacity of 900,000 feet of lumber, and is to be launched on or before the 15th of June next.

THE Tacoma *News* gives the dimensions of two logs recently photographed on the line of the Northern Pacific railroad, which will give some idea of the size of western timber. The picture shows two short sections of logs, one a red fir and the other a spruce, on a platform car. The dimensions of the red-fir log were: Diameter, 95.95 inches, or nearly eight feet. The hight of the tree from which it was cut was 295 20 feet; years of growth, 153. Spruce log: Diameter, 8.40, or nearly eight feet six inches; hight of tree, 196 9 feet; growth, 277 years. Inside of a century most of the forests that take from 200 to 700 years in growing will be destroyed.

THE Pacific Coast Steamship Company has discontinued the outfitting establishment it maintained at the junction of Davis, East and Vallejo streets. Some 80 men were employed there, and all the work necessary on the steamers was done in the shops. Now, however, the work will be let to the lowest bidder among outside firms, and thus business will be made a little more lively for shipwrights around the front. Michael J. Fitzgerald will take charge of the overseeing for the company in place of Theodore H. Downing, who was superintendent of construction.

H. S. LUBBOCK, Supervising Inspector of Steam Vessels for this coast, has returned from Washington, where he went to attend the annual meeting of the supervisors and inspectors from all parts of the country. This convention, Mr. Lubbock said, has changed the form of the test pieces to be taken from boiler plates, and has also introduced a new rule requiring all inspectors to bore through the shell of boilers which have been in use over 12 years. This is done in order to ascertain the weakest part of the boiler, which will only be licensed to carry a pressure of steam proportionate to the weakest spot.

GRIFFITH GRIFFITH, the pioneer worker in the granite industry of this State, died in San Francisco recently. His death removes one of the most promising and enterprising men of Placer county, and will be a heavy blow to the prospering town of Penryn, which owes its creation and growth to him. Mr. Griffith's first quarry of importance was opened in 1853 or 1854, near Mormon island. In 1864, he located a quarry at Wildwood, Placer county, on the line of the Sacramento, Placer & Nevada railroad. He afterward moved to Penryn and opened a quarry there. In 1874, Mr. Griffith erected at the Penryn quarry the first polishing mill in the State.

AS an evidence of the interest shown in salmon packs of the British Columbia waters, it was learned from Mr. Locke, who has just returned from Victoria, that his firm alone in five days of one week placed 158,000 cases of Alaska salmon, and that two other San Francisco brokers placed 30,000 cases, and a prominent Chicago operator purchased for Eastern sales 75,000 cases, making the total movement of Alaska fish 263,000 cases. Of canned fruits and vegetables, last year's pack was far in excess of any previous year, and yet, owing to the excessive tariff, 10,000,000 pounds less were shipped last January than in January, 1888.

THERE have just been turned out at Frank's tannery, San Mateo, two and a half tons of walrus hide. A year's time was consumed in this process of tanning, the hides when finished averaging an inch and a half thick. Walrus leather is used by jewelers for polishing and is valued at $1.50 per pound. Also at the tannery are a lot of hides imported from Spain and supposed to make the finest harness leather in the world. This tannery is the only one on the coast that uses imported raw material, the latest improvements that have been made increasing their facilities so much that hides enough cannot be procured in this market.

THE Risdon Iron Works of this city have in their shops a complete new set of triple-expansion engines for the Australia, designed to give her an increased speed of two knots per hour on a consumption of ten less tons of coal per day. The boiler-shops of the Risdon now present a scene of great activity, two boilers, the largest and strongest ever made on the Pacific Coast, being in course of completion there for the steamship Australia. The two boilers are now lying side by side with their shells completely riveted, each rivet being subjected to a hydraulic pressure of 97 tons. Some 200 men are at present employed in the boiler department.

PERHAPS the most interesting of all the departments of the hat industry is that of cloth hats and caps, boys' wear and military and conductors' goods. This branch is being carried on very successfully in this city by a large establishment, which, until recently, was located on Sansome street, but which has removed to a big building on Market street, where it has increased facilities for manufacture. There are from 30 to 40 girls at work in the factory, and business is very good for the season. The company makes nearly all of the caps worn by the conductors and brakemen of the Southern Pacific Company, and has made 1500 new caps for the employes of Wells, Fargo & Co.

GREAT success has attended the labors of our local piano manufacturers. They started out a dozen years ago with a determined effort to overcome the competition of the outside trade, and although the attempt seemed Quixotic, they have proved themselves equal to the task. It is safe to say that more than one-half of the pianos now being purchased on this coast are of Californian manufacture. It will be interesting to know that one of our large manufacturers has succeeded so well in the Eastern markets that he will build a factory in New York where piano-work begun here will be finished and sold. Agencies are being established by the same manufacturer in London, Paris, Vienna and other foreign cities. Over 20,000 instruments made in the local factories of the firm referred to are now in use.

THE new 10-story *Chronicle* building, in this city, is rapidly advancing. On Kearny street toward Market the blocks of stone facing are in position for a length of ten feet of the frontage and a hight of about 12 feet. The stone is light brown in color with more of a grayish tinge than ordinary Connecticut brownstone. It comes from the Seepe quarries of Ventura county, where it is being specially quarried for the *Chronicle* building. In point of hardness it is scarcely second to granite, and the same rates are charged for cutting and facing it as for the latter stone. A penknife make no impression upon it, which cannot be said of the Flagstaff, A. T., stone. The latter cuts easily with knife or chisel and is a less durable material.

SAN FRANCISCO has made as rapid advances in electrical science, and especially in the adaptation of anything new in electrical improvements, as any other large city in America. The many small uses to which electricity has been put and which have been introduced here are surprising to one who, for the first time, makes inquiry into this branch of the science. In the past few months, for instance, there has been a very large demand for electric bells, for doors and for burglar alarms, servant calls and other purposes. This is owing to a cheapening of the prices of these useful instruments, but more particularly to their neatness and the great improvement over old-fashioned articles, of which they are taking the place.

THE work of digging the tidal canal between San Leandro bay and Oakland harbor has commenced. The contract was let to the San Francisco Bridge Company by Colonel Mendel, and the contractors have been very busy in getting ready for operations. They have built quarters for the men and have two large excavators on the ground. J. S. O. Hamilton is the superintendent, and he has given an outline of the way the work is to be finished. A large dam is to be built around the estuary near the cotton-mills, and behind this the mud and earth will be thrown, making very substantial grounds for factories, which will then be on the line of deep water. When the canal is finished, which will be in about a year, the city of Alameda will be an island. The canal from the San Leandro bay will make a very strong current in the Oakland harbor, which will keep the channel always scoured out and free from mud. About 200 men are given employment.

IN closing contracts for completing the U. S. war vessel Monadnock, $100,000 worth of contracts for the ship will be distributed on the Pacific Coast, the Union Iron Works some weeks ago securing the contract for the boiler plating required in the ship. The following are among the list of successful bidders: Five thousand two hundred and fifty feet of white oak, board measure, 50 white oak knees, 25 hackmatack knees. The contract was awarded to A. Powell of San Francisco for $2720; 68,140 feet of Oregon pine deck planks and 15,000 cubic feet of Oregon pine timber. The contract was awarded to W. Walker of Vallejo for $11,118; 92,000 feet of redwood plank boards. The contract was awarded to W. Walker of Vallejo for $3169; 20 700 feet of white ash, W. Walker of Vallejo, $2262; 1415 feet of white ash boards, A. Crawford, San Francisco, $110 74. The same firm, cotton waste, $39.20; 10,800 feet of black walnut, mahogany, maple and cherry, W. Walker of Vallejo, $2713; 10,000 feet of cypress and cedar, W. Walker of Vallejo, $1000; 475 white oak staves and headings, W. Walker of Vallejo, $194; 25 French plate looking-glasses, W. F. Whittier, San Francisco, $162; 65,770 pounds of wrought iron, round and square, Geo. W. Gibbs & Co., San Francisco, $1302; 400 pounds round steel, Geo. W. Gibbs & Co., $114; 3700 pounds iron cut nails, awarded to Dunham, Carrigan, Hayden & Co., San Francisco, $250; 1000 pounds zinc, Austin & Phelps, San Francisco, $75; 3000 pounds block tin, Dunham, Carrigan, Hayden & Co., San Francisco, $780; 60 dozen locks, hinges, bolts of brass and iron, W. R. S. Foye, San Francisco, $385; hardware of all descriptions to the Dunham, Carrigan & Hayden Company of San Francisco, $2670; 6900 pounds white lead in oil, W. F. Whittier of San Francisco, $407; the same firm, 3500 pounds of white zinc in oil, $227; the same firm, for colored paints, dryers' shellac, cork, etc., $861; also 660 gallons of linseed oil, $412; 500 gallons of varnish and spirits of turpentine to C. M. Yates, San Francisco, $318; the same firm, 20 dozen assorted paint-brushes, $128; 8 leather hides, to W. R. S. Foye, San Francisco, $96; W. F. Whittier, San Francisco, 45 gallons of alcohol $101, 32 gallons of fish oil $13, window glass $12, 19 barrels of North Carolina pitch $54; bulb T bars of steel for the hull, Dunham, Carrigan & Hayden Company of San Francisco, $12,580; the same firm, cone-head steel rivets, $810; the same firm, bulb T bars of steel for turret, $3490; the same firm, T bars, stiffeners for turret, $22; the same firm, angle bars of steel for the turret, $2415; the same firm, rivets for turret, $668; angle steel bars for the hull, Austin & Phelps of San Francisco, $11,900; the same firm, T bars, stiffeners, for the military mast, $55; same firm, steel angle bars for military mast, $39.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most *reliable* advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

PARROTT & CO.,
306 California St., San Francisco, Cal.

EXTENSIVE GOLD MINE FOR SALE

To be sold at public auction by the undersigned, at the Merchants' Exchange, in the City of Halifax, on Thursday the Fourteenth day of March next, at twelve o'clock noon, that extensive, valuable and well equipped Gold Mine known as the Dufferin Gold Mine, situate on the Atlantic coast, about ninety miles east of said city. Daily mail from Halifax. Telegraph office at Salmon river, four miles from the works. Salmon river harbor never freezes, and is safe and easy of access. The mine embraces 342 acres, each 1320 feet, all in one block. The entire area measures fifteen hundred feet in width across, and eight thousand two hundred and fifty feet along the lodge. The leases have nearly fourteen years to run, and can at any time be renewed for a period of twenty one years, upon payment of two dollars per area. Within this area is a belt of veins dipping on each side of an anticlinal. They have been found by tests made on the surface to extend upwards of 4000 feet. The ore has been partially removed to a depth of 200 feet over a distance of about 700 feet, and is valued at averaging about 70 feet over an additional 1400 feet in length, or thereabouts. The veins are of various width, the largest averaging about ten feet of solid quartz.

This mine was discovered in the Autumn of 1860, but was not worked to any extent until the Autumn of 1861. It has yielded up to the end of November, 31,000 ounces of gold from 64,000 tons of quartz, according to the sworn returns made to the Mines office. The gold can be produced at a cost which will leave a very handsome margin of profit.

The mine is operated by machinery worked by water power, the power being transmitted by a line of wire rope running from the water wheel to the mine, a distance of about 4,750 feet, and lying parallel to the outcrop of said veins, at a distance therefrom of about fifty feet. The Salmon river crosses the property twice. It supplies the hoisting and pumping power, and the same water is afterwards used to drive the crusher. The latter has thirty-eight stamps, and there is ample water power to operate three times that number. Sixty stamps can be operated with present machinery. Of the 120 horse-power existing for pumping and hoisting only about twenty-five is used. There are about 700 acres of well timbered and well watered land owned with the mine. This partly covers the areas, and where it does not immediately adjoins them. It is also provided with a steam plant to operate hoisting gear and pumps in case of accident to the transmission power, a sawmill, sufficient for the requirements of the property, a tramway from the mine to the crusher for carrying quartz, and stables, offices, and boarding-houses, sufficient to accommodate a large number of employees.

The mine is owned and has been operated by a partnership, and owing to the death of one of the principal owners it has to be sold to enable his estate to be settled. A good title will be given.

Terms, ten per cent cash, balance within thirty days from day of sale. The deposit to be forfeited in case the purchaser fails to complete the purchase within that time. Further particulars can be had on reference to N. H. MEAGHER, Q. C., Bedford Row, Halifax, or to JAMES DUGGAN & SONS, Auctioneers, Bedford Row.

VALUABLE BOOKS ON MINERALS AND MINING.

A PRACTICAL MANUAL OF MINERALS, MINES AND MINING; comprising suggestions as to the localities and associations of all the Useful Minerals; full descriptions of the most effective methods of both the qualitative and quantitative analyses of each of these minerals, and hints upon the various operations of mining, including Architecture and Construction. By Prof. H. S. Osborn, LL. D. Illustrated by 171 engravings. 8vo. 287 pages. Price.....$4 50

☞ A descriptive circular giving the full contents of the above book sent free to any one who will send his address

A TREATISE ON METALLIFEROUS MINERALS AND MINING. By D. C. Davies. With 148 illustrations. 12mo, 432 pages. Price..$5.00

MINE DRAINAGE. By Stephen Michell. 8vo, 277 engravings. Price.....$6.00

A TREATISE ON EARTHY AND OTHER MINERALS AND MINING. By D. C. Davies. With 76 engravings. 12mo. Price.....$5.00

THE PROSPECTOR'S HAND BOOK. A Guide for the Prospector and Traveler in search of Metal-bearing or other valuable Minerals. Illustrated. 12mo. Price.....$1.50

MINERALOGY SIMPLIFIED. Easy Methods of Identifying Minerals, including Ores, by means of the Blowpipe, by Flame Reactions, by the Spectroscope and by Humid Chemical Analysis, based on Von Kobell's Tables for the Determination of Minerals, etc. By Henri Erni, M. D. Illustrated. 12mo. Price...$3.00

UNDERGROUND TREASURES; HOW AND WHERE TO FIND THEM. A Key for the Ready Determination of Minerals within the United States. By James Orton. Price.....$1.50

☞ The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

☞ Our New and Revised Catalogue of Practical and Scientific Books, 84 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

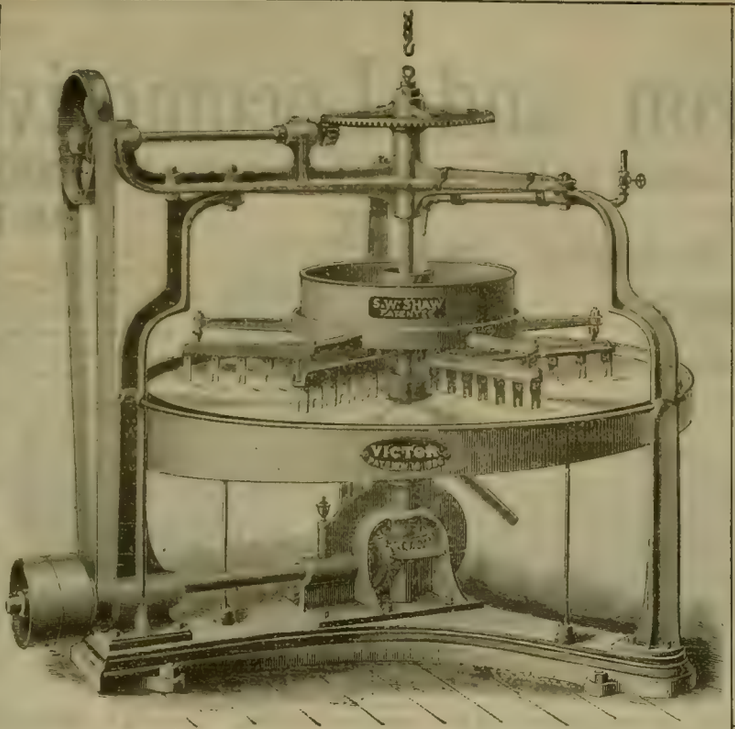
SAFE DEPOSIT BUILDING, ROOM No. 2



THE VICTOR CONCENTRATOR,

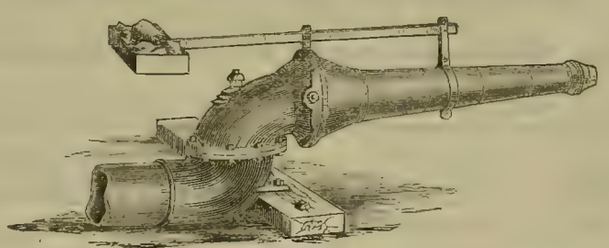
Having passed the experimental stage, is now offered to the consideration of the mining public, in full confidence that it will meet satisfactorily all reasonable requirements. In operation it is unlike any other machine of its class. The concave disc having a rotary reciprocal motion, causing the waste sands to flow over its periphery continuously, while the sulphurets are also drawn continuously through its center, the whole process being automatic and complete. The Batea in the hands of an expert is known to be the nearest to perfection for concentration. This is the principle upon which this machine works. The advantages gained are:

1. Greater capacity with more perfect work.
2. Simplicity of construction and management.
3. When used as an amalgamator it has no equal.
4. The first cost is less than other machines of much less capacity.
5. The shipping weight is less than 1000 pounds.

Mine owners and millmen are invited to carefully examine the Victor before deciding upon their concentrating works. Address

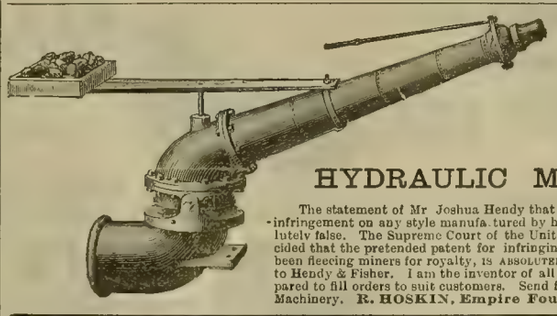
S. W. SHAW, or N. W. SPAULDING,
17 and 19 Fremont Street, SAN FRANCISCO.

IMPROVED FORM OF HYDRAULIC GIANTS.



THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture. We guarantee purchasers of this form of Giants against all costs, expenses or damages which may arise from any adverse suits or actions at law. We are further prepared to furnish **Single-Jointed Giants** when required. Prices, discounts and Catalogues of our specialties of **Hydraulic Mining Machinery** sent on application.

JOSHUA HENDY MACHINE WORKS, 39 to 51 Fremont St., San Francisco.



HOSKIN'S IMPROVED ONE-JOINTED HYDRAULIC MACHINE.

The statement of Mr Joshua Hendy that ANY STYLE of machine is an infringement on any style manufactured by him, he knows to be absolutely false. The Supreme Court of the United States on March 19th decided that the pretended patent for infringing, which he has for years been fleecing miners for royalty, is ABSOLUTELY VOID, with costs of suit to Hendy & Fisher. I am the inventor of all styles in use, and am prepared to fill orders to suit customers. Send for list of prices of Hydraulic Machinery. **R. HOSKIN, Empire Foundry, Marysville, Cal.**

HOISTING ENGINES FOR MINES.

54-INCH BY 16 FEET STEEL BOILERS IN 2 SHEETS.

STEAM USERS, ATTENTION!

The engraving represents our standard 54 in. x 16 ft. Boiler. These boilers are made of homogeneous STEEL, and the shell, as shown, being in TWO PIECES, the advantage of this will be readily appreciated by steam users.

There are NO SEAMS in the fire to leak, nor loose rivets to contend with, caused by the continual expansion and contraction of the plate on account of the unequal distribution of the heat under the boiler, the bottom presenting a smooth, even surface which can be easily cleaned. We place a manhole at the back end above the tubes, and one in the front end under the tubes.

The FRONT MANHOLE gives free access to the sheet over the fire, THE VITAL PART OF EVERY BOILER. This point is often overlooked by purchasers, and boilers are supplied with a small hand hole, and the remaining space filled with tubes which allows absolutely no access for cleaning, and in a short time tubes and sediment are one solid mass, and instead of gain in efficiency by a few feet of tube surface, the result is a positive loss.

SPECIFICATION OF BOILER AND FIXTURES:

1 Boiler, 54 inches diameter by 16 feet, with 46 3½-inch tubes; Shell, 5-16; Heads, 7-16.
1 Steam Drum, 36 inches diameter by 72 inches long.
1 Breeching.
1 Smokestack, 30 inches by 60 feet, Nos. 12 and 14 Iron.
300 feet galvanized strand for Guys.
1 C. I. Front, complete.
1 Foundation Plate for front.
1 Set Grate Bars for coal or wood.
1 Back Bar Bearer.
1 Ash Cleaning Door and Frame.
1 Back Arch Plate.
1 Set Binder Braces and Bolts for Brickwork.
1 Stand for back end of Boiler.
1 Steam Gauge and Syphon.
1 Glass Water Gauge, complete, with column and 3 Gauge Cocks.
1 Safety Valve.
1 Stop Valve.
1 Feed Valve.
1 Blow-off Valve.
1 Check Valve.

These Boilers are tested to 150 pounds hydrostatic pressure and are intended for a working pressure of 100 pounds. Total weight of Boiler and fixtures, 17,000 pounds.

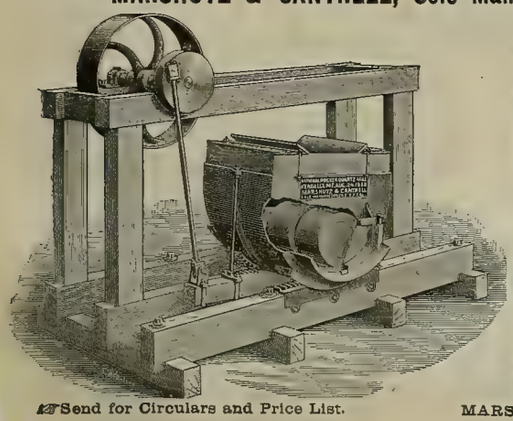
CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

THE BUFFALO CONSOLIDATED GOLD Mining Company, Sierra City, Cal., Ernest Busch, Superintendent. Stock divided into 600,000 shares at $1 per share. The property comprises 5 locations. Ore finely decomposed, carries coarse gold. Size of ledge: Tunnel No 1, 32 ft.; No. 2, 9½ ft.; No. 3, 10 ft. Fine black decomposed rock interspersed with white quartz. New 10-stamp mill run by a Pelton Wheel, blacksmith shop and boarding house. Stockholders: Ernest Busch, Hugh Murray, Frank Cook, J. G. Lee, Henry Carpenter. For further information apply to Ernest Busch, Sup't, or Hugh Murray, Sec'y.

THE CALIFORNIA CONSOLIDATED Gold Mining Company, Sierra City, Cal., A. Schubert, President; Alvin Fischer, Secretary; A. Leller, Superintendent. Divided into 300,000 shares at $1 each. Property comprises two locations. Ore assays $7 per ton, average. Coarse gold, solid rock; vein from 15 inches to 2 feet wide. Tunnel No. 1 in 120 feet, and prospects well. No. 2 just begun. Stockholders: Alvin Fischer, A. Schubert, Gus Fischer, F. L. Fischer, Anton Fischer, Fred Fischer. For information concerning stock, etc., apply to F. L. Fischer, Sierra City.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, March 7, 1889.

General trade continues only fair, yet it is fully up to previous years in this month. The outlook, at this writing, is of the most encouraging character, particularly so if well distributed rains are had on this coast, with large deposits of snow on the mountain ranges. Those who make the climate of this coast a special study, express themselves as being very confident of heavy rains and large deposits of snow within the next 30 days. With this an assured fact, new life will be instilled into all leading industries, with its reflection in general trade. The local money market is reported easier, with the tendency toward a lower rate of interest in the immediate future. It is claimed that more money will set this way for investment. In the speculative markets wheat has engaged more general attention, which created a better call for funds from operators. Local securities have been quite active. The decline in Spring Valley Water Co.'s stock affected the entire list, but with its steadying caused a better feeling along the line. It is claimed that inside manipulators are buying the stock, while in Hawaiian Commercial it is asserted that the inside has sold and are still unloading at present prices. In mining stocks the market has dragged at lower prices. Present appearances warrant the assertion that about everything is being brought to bear to depress the market so as to concentrate certain stocks, and in furthering this object it is very difficult to get reliable news from the Comstock mines outside of the State reports that new drifts and crosscuts have been or are about being started. It is confidently claimed that work in several of the mines which promised the best results within a short time, has been stopped, evidently for stock manipulation, as were also the levying of assessments with reports of others to follow.

The news from the Quijotoa, Bodies and Tuscarora mines is still of favorable character. From the Comstock mines we are advised of an improvement in Hale and Norcross, Savage, Ophir and Crown Point, while from Crown Point and Con. Virginia advices are of the very best character. In Challenge on the 300-foot level, important work is being done. The joint Union-Mexican crosscut, it is claimed, ought to be in ore some time in this month. It is reported that 60 stamps in the Nevada mill will soon be started, with probably 20 run on Hale and Norcross, and the others on Chollar and Potosi ore. It is also said that the California Panmill with 40 stamps will soon start up. Ore shipments from the Yellow Jacket above the milling grade will probably be commenced the coming week. Crown Point's ore is above the milling grade. The Hale and Norcross ore is increasing in assay value.

The San Francisco bank clearings during the month of February were as follows:

	Clearings.	Balances.
1889	$58,555,638	$8 658,179
1888	63,457.972	8,931,824

The coinage at the mint in this last month aggregated as follows: Double eagles, $1,020,000; eagles, $420,000; dimes, $2200. Total, $1,442,200.

The export value of merchandise shipped by sea from this port last month aggregated $2,566,597, against $2,858,643 in February, 1888.

On March 1st there was in the hands of the Assistant United States Treasurer at this port $35,963,409.50 in gold coin, $18,290,205 in standard silver dollars, and $6,821,115.25 in fractional silver.

The last steamer leaving for China took out to Hong Kong, 67,139 Mexican dollars, $7955 gold dust, and $72,000 silver bullion. For Bombay the shipment was $47,000 in silver bullion.

A mining expert of acknowledged ability is on the Comstock inspecting the Confidence and other mines of the Gold Hill group in the interest of stockholders. His report is looked forward to with interest by a class of large outside holders of the stocks in those particular mines.

COPPER—Cables received last Wednesday reported a decided decline in the market value of copper, with fears entertained that the French syndicate formed in October, 1887, was on the eve of a collapse. Color was given to this impression by the suicide of Mr. Deufert Rochereau, a director of the Comptoir d'Escompete, in consequence, it was asserted, of the decline in copper and a consequent fear of a run on the bank. The workings of the syndicate were set forth at considerable length in last week's issue of the MINING AND SCIENTIFIC PRESS, to which we refer patrons for the information. The events of the week only confirmed the tenor of our article, that the syndicate would have to adopt measures to restrict the output of copper, or sooner or later financial ruin, even though backed by the wealth of the Rothschilds, would be the result. This the controllers of the syndicate fully realized, and determined to force a decline in the price of copper even at the expense of losing some of if not all the profit made during the past two years. Bearing on this, we reproduce from an exchange the following interview with Colonel Horace D. Ranlett, who is probably the best authority on the subject. "The collapse of the syndicate," he said, "is out of the question. It is backed by the wealth of the Rothschilds, and is without doubt working at a loss, and putting down the prices to get control of all producers, and thereby limit production. According to latest advices, the syndicate has $60,000,000 worth of copper on hand, enough to supply the world for two years. When the syndicate was organized, about 18 months ago, copper was selling for 10 cents a pound, a price that did not pay. It is now selling for 15 cents, but will speedily descend to the old figure unless the output is restricted. The syndicate aimed to control the market of the world, but failed to limit the production. The consequence is, the vast amount of metal now on hand, which the syndicate will use in bearing the companies until it gets control of their stock, or forces them to agree to diminish production."

There is another thing quite important within itself, that evidently has a direct bearing on the decline in copper; viz.: the capitalists controlling the French syndicate are reported to have had large lines of stocks in the three foreign companies, the price for which was based on that of copper. Buying these stocks at a nominal figure, they were advanced as copper went up to high figures. At the higher figures the cupidity of outside speculators caused them to rush in and buy, which enabled the members of the syndicate to unload at big profits. What this amounted to it is difficult to say, but it can be judged by the decline which has since set in and reported in the copper stock at the East by the telegraph to be over $19,000,000 within the past six months. Of necessity the decline of the stock in the three leading companies in Europe, whose stock was based on the price of copper, must have been proportionately as great.

COAL—The market is fairly steady. It is claimed that with a continuance of the present rain prices will be more apt to appreciate than decline. The imports the past week were as follows: From Nanaimo, 6640 tons; Seattle, 5405; Departure bay, 807; and overland, 30¼. Total, 12,882 tons.

SILVER—The market held to steady prices at from 93⅛@93¼c up to Wednesday, when a weaker tone was manifested, resulting in a decline to-day, now being quoted at 92⅞@93c, in sympathy with a drop of 1-16 d in London and ⅛c in New York. Exchanges being weaker are against silver in our market. The output of silver on this coast is still light, with no material increase looked for in the near future, owing to the gold percentage showing an increase in the ore milled by the Comstock mines.

QUICKSILVER—Receipts the past week were 600 flasks by J. R. Randol, 34 by H. M. Newhall and 53 by Redington. The exports by sea were 440 flasks to Guaymas and 1 to Central America. The market has shaded off. The call continues only fair. The present rains, it is claimed, will probably cause a better demand.

LEAD—The market is reported steady, with a fair call ruling.

IRON—The market continues inactive. At this writing a more cheerful feeling is brought about by to-day's rains, which are said to be general. With the crops assured by well-distributed rains, many contemplated improvements, it is thought, will be started.

TIN—Pig is still heavy, while plate has eased off under freer receipts and more disposition to let go. The demand from Alaska is less marked, while the Columbia and Sacramento canners take sparingly. Fruit-canners have contracted to some extent to arrive. Receipts the past week aggregated 9524 boxes overland. The export clearance was 18,252 boxes to British Columbia.

Eastern Metal Markets.

By Telegraph.

NEW YORK, March 7, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42⅝	93½	$16 50	$3 70	$21 55
Friday	42 9-16	93½	16 25	3 70	21 65
Saturday	42 9-16	93½	16 30	3 70	21 60
Monday	42 9 16	93½	16 25	3 72½	21 50
Tuesday	42 9-16	93½	15 75	3 72½	21 50
Wednesday	42 9-16	93½	15 60	3 70	21 00

Quicksilver has fluctuated to a lower level. Tin has eased off some, but the tone is fairly steady at the close. Lead is more inquired for, with several large transactions reported. Copper held up at a lower range up to Tuesday, when under disquieting news from Europe, holders forced sales, causing lower prices. At the close there was a stronger tone, owing to large operators standing under the market.

At the Sutro tunnel they have returned to the old rule and ceased working on Sunday, there being now only repair work to be done. While pushing through the drain drift to connect with the Crown Point, the men were obliged to work on Sundays.

Dredging Operations at San Diego.

A few months since we made mention of the fact that a dredger was being built in San Diego for use on Glorietta bay, a portion of San Diego bay. The machine has been finished and is at work. G. L. Pierce and A. B. Bowers returned from there last week and state that the machine is doing excellent work. It is called the "Bowers dredge No. 3," being the third of the kind built. This was made under the supervision of Mr. Pierce of this city. In a report to the Board of Directors of the Bowers Dredging Company that gentleman says:

The dredge was started up on the 29th of January. In the first ten days little was done other than repairing some small breakages arising from the inexperience of the workmen and in familiarizing the new hands with the working of the machine. Since then the dredge ran steadily up to the time of my leaving on the 22d inst., with exception of delays caused by low tides and changing the position of the machine. Everything is in perfect order, running smoothly, without heating of bearings, and giving entire satisfaction.

The material in which the dredge is working consists of about 90 per cent of sand and shell with sufficient clay to fill the interstices. For several inches from the surface it is quite soft, but gets harder and more compact as you go down, and at the depth of about three feet becomes so hard that the iron-pointed vertical anchor or "spud," weighing 2½ tons, and dropping 12 feet, will penetrate but three inches, or but eight inches on being dropped three times.

The feeding device is a valuable improvement, resulting in a great saving of time, and enabling the machine to be fed forward for a new series of cuts in considerably less than one minute, even when the pivotal anchor has to be raised and dropped three times on account of the hardness of the bottom. This forward feed has sometimes been made in 25 and often in 30 seconds. As a full swing of the dredge, in ordinary material, occupies only about five minutes in shallow cuts, where the machine must be fed forward on every swing, this improvement effects a saving of fully one-half of the time.

The average results of repeated tests made by me are as follows:

1st. The quantity of clear water raised to an elevation of ten feet and delivered through 258 feet of pipe, the end of the discharge pipe being dropped to an elevation of six feet above the water, is from 19,800 to 20,000 gallons per minute; the pump making 160 revolutions, and the direct-acting Westinghouse engine showing an average of 165.77 indicated horse-power.

2d. With the foregoing number of revolutions and length and elevation of pipe, when working in the lower and harder portion of the excavation, the machine cuts, raises, and delivers 4.19 cubic yards of said sand, shells and clay per minute, with an expenditure of 188.79 indicated horse-power on the engine that drives the pump.

3d. Under the same conditions, when working at a depth of five feet below the surface of the bottom, the delivery was 7.66 cubic yards per minute and the indicated horse-power, 192.75.

4th. When working to a depth of three feet from said surface in the less compact material, the delivery was 12 79 cubic yards per minute, with an average indicated horse-power of only 179 98.

On a run of 5 hours and 20 minutes, the total output was 3030 cubic yards, or an average of 9.46 cubic yards per minute.

The coal was of good quality, having an evaporative power of about eight. The average consumption was 800 pounds per hour. The total capacity of all the engines is something over 300 horse power. You are aware that I have built many dredging machines of various kinds and am familiar with all kinds now in use. I congratulate you on having a machine of moderate cost (many machines of less capacity cost from $75,000 to $150,000), economical working and with many advantages for this class of work over all others of which I have any knowledge.

Sucoessful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

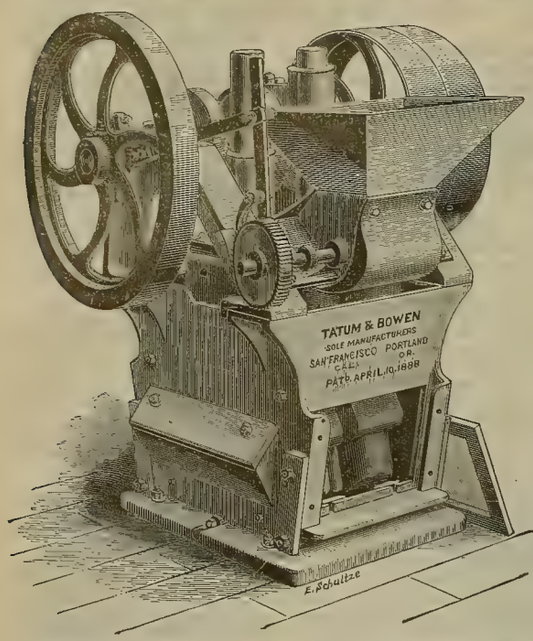
HARVESTING MACHINE.—Jabez Draper, Stockton. No. 398,711. Dated Feb. 26, 1889. This invention relates to certain improvements in the running gear for harvesting machines of that class in which the header and thrasher are connected together and hauled about the field, the grain being cut, thrashed, separated and cleaned during the operation. The invention consists in certain improvements in the turn-table and single front wheel upon which the front portion of the machine is supported.

PLOW.—James and William Paterson, Stockton. No. 398,648. Dated Feb. 26, 1889. This consists of a series of concavo-convex disks centrally journaled so as to turn freely on the ends of arms which project radially from hubs fixed upon a main bearing and driving shaft, through which power is applied to rotate the arms and disks, so that the latter enter and leave the soil intermittently. Various devices have been employed in the place of ordinary plows for turning the soil, some consisting of blades mounted spirally upon a shaft, said blades turning continuously in the soil, others consisting of disks mounted on shafts so their edges turn continuously in the soil, and various modifications of these devices. This invention differs from these in having a series of independent cup-shaped disks so mounted as to turn freely in the ends of radial arms extending outwardly from the driving-shaft, so that said disks are caused to enter the ground and rotate therein intermittently instead of continuously.

SAFETY ATTACHMENT FOR ELEVATORS.—H. O. Hooper, S. F., assignor one-half to John Bresmen, Eureka, Humboldt Co. No. 398,728. Dated Feb. 26, 1889. This safety attachment for elevators consists of a grooved or channeled weight traveling upon a guide or guides and connected with the elevator cage by a rope passing over pulleys at the top, and, in connection therewith, of a wedge-shaped weight fitting into the groove or channel, said wedge being suspended at a point above the channel so as to allow the weight to travel loosely unless the suspending-rope of the cage should break, when, by means of a lever-arm, the wedge falls into the groove or channel and bends between it and the guide-post so as to check the movement of the cage. In order to insure the bending of the wedge against the face of the guide, this face is made slightly tapering from bottom to top, being thinnest or narrowest at the bottom, and thickest at the top, so that as the weight travels upward the wedge-shaped space will continually become narrower, and when the wedge is fixed into the channel the compression wil be made stronger and stronger until the whole is rought to a stop.

A. B. HULL, who has been engaged in mining matters for many years on this coast, died in Oakland on Monday. He has been a director and vice-president of the Consolidated Virginia, California, Gould and Curry, Best and Belcher, Sierra Nevada and other prominent corporations, and was vice-president of the Consolidated California and Virginia Co. at the time of his death.

A. W. HAVENS has been elected vice-president of the Mexican Mining Co., vice A. B. Hull, deceased, and Herman Zadig to the Board of Directors.



—THE—

PERFECTED

DOUBLE

Economic

Quartz

Mill.

Attached to each Mill is an effective

Automatic Ore Feeder.

THE CRUSHING is done by the rapid rocking movement in OPPOSITE DIRECTIONS of two heavy castings, the bottoms of which are slightly circular in form, and each provided with four shoes.

The Mill is a closer Gold-Saver and catches a larger percentage of the Clean-up in the Battery than any other Mill.

It costs less, in proportion to what it will do, than any other mill. There are no working parts to buy for it, no matter how long it is used, except shoes and dies. Capacity of Mill, 6 to 10 tons per day. Weight of Mill, complete, 6400 pounds.

We manufacture, to go with the Mill, an

IMPROVED ROCK BREAKER.

E. E. EYRE, President. JAS. H. GRAHAM, Vice-Pres. & Manager. G. M. PINCKARD, Sec'y.

VULCAN IRON WORKS,

Successors to SAVAGE, SON & CO.,

135 to 145 Fremont Street, - - San Francisco, Cal.

MINING MACHINERY,

Stamp Batteries, Pans, Settlers, Etc. "Dodge" Rock Breakers, Pulverizers, Concentrators.

SAWMILL MACHINERY,

Refrigerating and Ice Machinery,

STEAM ENGINES,

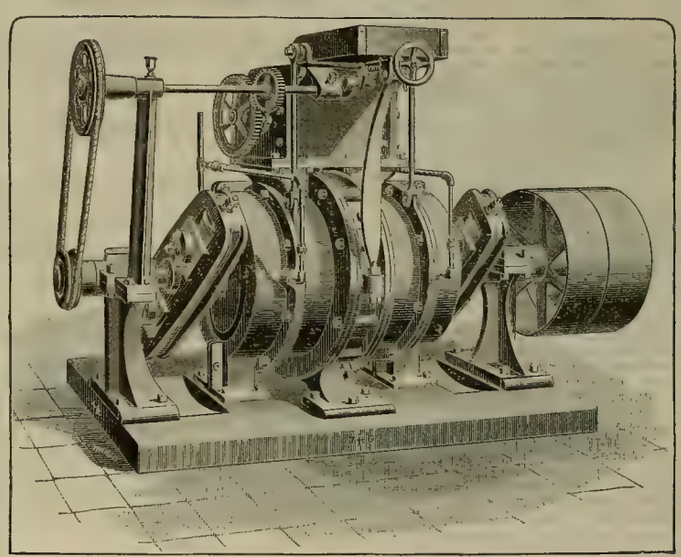
CORLISS, MYER'S CUT-OFF, PLAIN SIDE-VALVE.

Shafting, Pulleys, Hanger and Boxes, Etc.

Special machinery of all kinds. We have a large list of Standard Patterns, Gears, Pulleys, Boxes, etc. REPAIR WORK SOLICITED.

FRISBEE WET MILL.

This Mill, with a weight of less than 9000 pounds, has a capacity of three tons per hour of hard quartz to 40 mesh; is in successful operation and we guarantee its work as represented.



IT HAS NO MORE WEARING PARTS THAN CORNISH ROLLS,

And renewals will not cost over one-half as much as for stamps. Will run empty, or with small amount of ore without injury. The attention of parties having Cement Gravel is called to this Mill, as it will run 100 tons per day to No. 8 mesh; 30 to 35 H. P.

OUR DRY MILLS are the most economical ever built, and are extensively used with record of several years. No grinding in pans. Mill finishes to any fineness desired.

FRISBEE-LUCOP MILL COMPANY,

GIDEON FRISBEE, Manager, - - - 461 Howard St., San Francisco.

HOOKER & LAWRENCE, Gen'l Ag'ts, 145 Broadway, New York.

RAND ROCK DRILLS

AND AIR COMPRESSORS.

Of the Machine-Mined Mineral in the U. S., in 1887, three-quarters of the Iron Ore and two-thirds of the Copper Ore were mined with Rand Drills.

THE HIGHEST AMERICAN TUNNELING RECORD.

THE STANDARD

American Rock Drilling Machinery

For Mines, Tunnels, Quarries, Sewers, Grading, etc.

RAND DRILL CO.,

23 PARK PLACE, NEW YORK.

AMALGAMATING MACHINERY.

Stamp Mills for Wet or Dry Crushing. Huntington Centrifugal Quartz Mill. Drying Cylinders. Amalgamating Pans, Settlers, Agitators and Concentrators. Retorts, Bullion and Ingot Moulds, Conveyors, Elevators, Brucknerr and Howell's Improved White's Roasting Furnaces, Etc.

CONCENTRATING MACHINERY.

Blake, Dodge and Comet Crushers, Cornish Crushing and Finishing Rolls, Hartz Plunger and Collom Jigs. Frue Vanner & Embrey Concentrators, Evans', Calumet, Collom's and Rittenger's Slime Tables. Trommels, Wire Cloth and Punched Plates. Ore Sampler Grinders and Heberle Mills.

FRASER & CHALMERS,
MINING * MACHINERY,

Improved Corliss and Slide-Valve Steam Engines,
Boilers--Horizontal, Vertical and Sectional,
IMPROVED STEAM STAMPS.

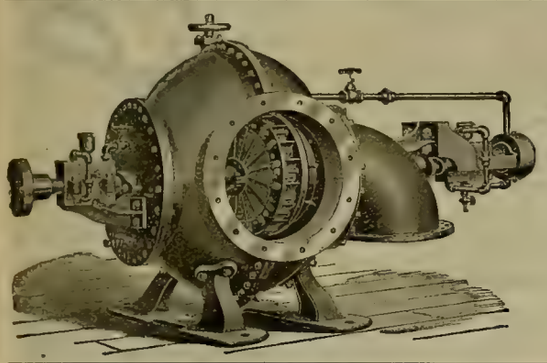
Hoisting Engines, Safety Cages, Safety Hooks, Ore Cars, Water and Ore Buckets, Air Compressors, Rock Drills, Etc. General Mill and Mining Supplies, Etc.

Pumping Engines and Cornish Pumping Machinery, Improved Water Jacket, Blast Furnaces for Galena and Copper Ores. Slag Cars and Pots, Roots & Baker Pressure Blowers, Suspended Tramways.

Sectional Machinery for Mule-Back Transportation.

General Offices and Works: FULTON & UNION STS., CHICAGO, ILL.

BRANCH OFFICES: NEW YORK, Room 43, No. 2 Wall St. DENVER, COLO., 1316 Eighteenth St. SALT LAKE CITY, UTAH, 7 Wes Second South St. LONDON, ENGLAND, 23 Bucklersbury, E. C. CHIHUAHUA CITY, MEXICO, No. 11 Calle de Juarez. LIMA, PERU, South America. JOHANNESBURG, TRANSVAAL, South Africa.



JAMES LEFFEL'S
Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

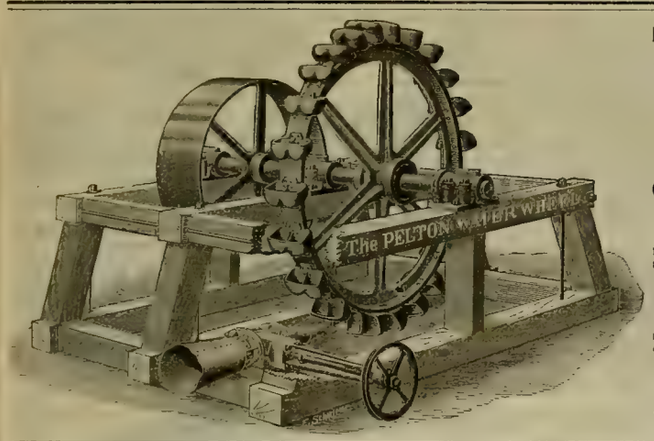
Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

JAMES LEFFEL & CO.,
Springfield, Ohio, or 110 Liberty St., New York.

FRASER & CHALMERS, General Agents, Chicago, Ill., and Denver, Col.

PARKE & LACY, General Agents, San Francisco, Cal.



THE PELTON WATER WHEEL

GIVES THE

Highest Efficiency of any Wheel in the World.

A MARVEL OF ENERGY AND POWER.

Over 600 in use on the Pacific Coast alone, aggregating upwards of 50,000 Horse Power.

It is not only most economical of water, but the most simple and reliable power for Quartz Mills, Compressors, Hoisting, Pumping, or any other purpose where water power can be used.

ELECTRIC TRANSMISSION.

Power from these Wheels can be transmitted long distances with small loss, and it is now being extensively used in this way in all parts of the country for producing both light and power.

☞ SEND FOR CIRCULAR. Address:

THE PELTON WATER WHEEL CO.,
120 First Street, - - San Francisco, Cal.

The BUYERS' GUIDE is issued March and Sept., each year. It is an encyclopedia of useful information for all who purchase the luxuries or the necessities of life. We can clothe you and furnish you with all the necessary and unnecessary appliances to ride, walk, dance, sleep, eat, fish, hunt, work, go to church, or stay at home, and in various sizes, styles and quantities. Just figure out what is required to do all these things COMFORTABLY, and you can make a fair estimate of the value of the BUYERS' GUIDE, which will be sent upon receipt of 10 cents to pay postage,

MONTGOMERY WARD & CO.

GREAT REDUCTION!

BATTERY SCREENS.
Best and Cheapest in America.

No imitation, no deception, no planished or rotten iron used. Only genuine Russia iron in Quartz Screens. Planished iron screens at nearly half my former rates.

I have a large supply of Battery Screens on hand suitable for the Huntington and all Stamp Mills, which I will sell at 20 per cent discount.

PERFORATED SHEET METAL

For Flour and Rice Mills, Grain Separators, Revolving and Shot Screens, Stamp Batteries and all kinds of Mining and Milling Machinery. Iron, Steel, Copper, Brass Zinc and other metals punched for all uses.

Inventor and Manufacturer of the celebrated Slot Cut burred and Slot Punched Screens.

Mining Screens a specialty, from No. 1 to 15 (fine).

Orders promptly attended to.

San Francisco Pioneer Screen Works,
21 & 223 First St., San Francisco, Cal
JOHN W. QUICK, Proprietor.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 500 South 10th St., Philadelphia. Branch Offices—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

Legislative.

In the Senate on Tuesday Langford's bill to abolish the office of State Engineer came up, and Sprague offered a substitute, which was adopted. It makes the State Mineralogist ex-officio State Engineer, at an increase in salary of $3000 a year. The office is to continue only two years. A motion by Heacock to strike out the salary was lost and the bill was ordered engrossed.

The bill providing for elections on the Australian plan has been defeated.

The General Appropriation bill two years ago aggregated $8,000,000. This year the Controller estimates that the aggregate will be twelve or thirteen millions.

The bill appropriating $40,000 for boring a gas well at the Stockton Insane Asylum has been passed by the Assembly.

The Mutual Insurance bill has passed both houses.

The Senate has passed the Colusa County Division bill.

Mining Share Market.

Though the market has been rather active this week, prices have been irregular. The following mining companies show, by their monthly statements, cash on hand on the 1st inst.: Alpha, $16,215.55; Alta, $35,872.82; Andes, $12,182.23; Best and Belcher, $1797.25; Benton, $95,572.62; Bodie, $30,876.52; Bulwer, $570.83; Bullion, $28,831.59; Caledonia, $13,903.84; Challar, $3136.35; Con. California and Virginia, $64,717.60 and unsold bullion amounting to $56,538.10; Confidence, $62,381.45; Con. Imperial, $16,407.79; Dudley, $152.91; Exchequer, $6866.10; Found Treasure, $100.42; Gould and Curry, $9084.84, and the balance of an assessment to collect amounting to $1175.40; Hale and Norcross, $5229 94, and the gold and other bullion to come in; Independence, $1993.49; Julia, $831.28; Lady Washington, $23,831.30; Locomotive, $1134-55; Mono, $10,797.81; Occidental, $11,001.21; Ophir, $8757.32; Overman, $20,668.56; Navajo, $34,461.83; Scorpion, $7989; Syndicate, $8754.71; Standard, $20,262.78; Union, $13,047.93; Utah, $1570.16; Weldon, $156.47.

The following companies have an indebtedness: Belcher, $15,616.91; Belle Isle, $3407.46; Challenge, $603.99; Commonwealth, $45,513.96; Crocker, $2479.33; Crown Point, $28,779.10; Con. New York, $5605.50; Del Monte, $653.96; Grand Prize, $40,959.66; Holmes, $3491.13; Kentuck, $1062.06; Mt. Cory, $49,817.96; Mexican, $763.31; Nevada Queen, $4013.24; North Belle Isle, $7440.82; North Commonwealth, $14,016.69; Peerless, $7400.92, with an offset in bullion valued at $5143.32; Potosi, $17,248.56; Savage, $17,267.25; Seg. Belcher, $12,360.92; Sierra Nevada, $2803.03; Peer, $6204.79.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

OAK CON. M. CO, Feb. 21. Capital stock, $100,000. Directors—O. P. Evans, E. A. Rix, L. M. Hoeffler, N. S. Farley and W. McP. Hill.

ALAMEDA SUGAR CO., Feb. 26. Capital stock, $25,000. Directors—L. C. Marshutz, W. T. Mau, T. G. Cantrell, E. C. Burr and J. N. Browning.

WEST COAST STEAMSHIP CO., Feb. 25. Capital stock $3,000,000. Directors—J. N. Knowles, Millen Griffith, A. K. P. Harmon, Henry Pierce and W. C. Dean.

ALKI CON. M. CO., Feb. 23. Capital stock $500,000. Directors—H. P. Wood, B. B. Keeler, J. H. Swift, Randolph Crimmins and H. L. Shannon.

TYRO M. & M. CO., Feb. 26. Capital stock $500,000. Directors — Francis C. Jarvis, B. G. Lathrop, Jas. M. Haven, Thos. E. Haven, John O. Doane.

MUTUAL GASLIGHT & FUEL CO., March 4. Object, to manufacture illuminating and heating gas. Capital stock, $3,000,000. Directors—Columbus Bartlett, Robert Dickson, John I. Kennedy, H. L. Coye and Sampson Tams.

SANTA CUEVA M. CO, March 4. Capital stock, $1,500 000. Directors—E. M. Railton, W. B. Saufley, C. H. King, G. E. Neal and Frank Cunningham.

YOUNG PEOPLE'S INSURANCE SOCIETY OF CALIFORNIA, March 4. Object, to mutually insure the members. Directors—A. S. Keser, W. J. Barnes, J. W. Bird, Fred Delature, John R. Mitches and Charles S. Thomas.

GEORGE W. GIBBS CO., March 5. Object to deal in iron and steel. Directors—Geo. W. Gibbs, F. A. Gibbs, E. A. Selfridge, H. J. Morton and H. T. Gibbs.

REDWOOD MANUFACTURERS' ASS'N, March 5. Object, to deal in redwood lumber. Directors—Geo. W. Chandler, E. L. Allen, John Dalheer, J. C. Hawley, Francis Korbell, T. H. Minor, E. C. Williams, Carl E. White, J. G. Jackson, Henry Wetherbel and E. L. Dingley.

SKAGIT CUMBERLAND COAL CO, March 6. Location, Skagit, Washington Territory. Capital stock, $5,000,000. Directors—Patrick N. Mackay, Wm. Johns, Duncan C. Mackay, Robert O. Oakley and Robert E. Doyle.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Con. California and Virginia, March 2, $64,850; Savage, 2, $8200; Justice, 2, $3337; Hanauer, Feb. 27, $2775; Moulton, 26, $14,016; Hanauer, 28, $2880; Hanauer, March 1, $2880; 2, $3550.

Mt. Diablo, March 5, $5677; total for February, $29,884; Confidence, $16,681; total for February, $48,709.

SAN JOSE'S water rates are reduced 25 per cent.

MINING SHAREHOLDERS' DIRECTORY.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, term of subscription, and give it their own patronage, and as far as practicable aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

IT is stated that Dr. H. W. Harkness of this city, president of the California Academy of Sciences, aspires to the position held by Major Powell, as Chief of the U. S. Geological Survey.

For New Subscribers—Something New and Rare.

PACIFIC COAST RELIEF CHART.

PHOTO-FACSIMILE.

With subscription paid one year in advance for this paper, and 10 cents to pay postage and mailing tube, we will send a fine Photoplate Relief Chart of the Pacific Coast, embracing California, Nevada, Oregon, Washington Territory, and part of Montana, Idaho and Utah. Photographed from a topographical relief model in plaster (5 feet 3 inches by 5 feet 6 inches in size), made recently by Isaac Winston and Prof. Geo. Davidson (the latter Chief of the U. S. Coast Survey on this Coast for the past 20 years).

While it does not take the place of an ordinary map, it illustrates, comparatively, the elevations and depressions of the principal mountains, valleys, rivers, lakes, ocean and bay-shores of the Pacific States and Territories, and makes a permanently useful, handsome and desirable picture for either library, office or home.

The charts are 19x24 inches, well suited for framing, if desired. It is as handsome, and even more durable, than an ordinary photograph. Seldom is so choice an article offered as a newspaper premium. Sent to old subscribers on the same terms on paying one year in advance of current date. Subscribe and secure this permanently valuable chart.

Address Publishers of this paper, No. 220 Market St., S. F

Testing and Working Silver Ores

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post free, $2.00. Sold by DEWEY & Co., Publishers, 220 Market St.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or of some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

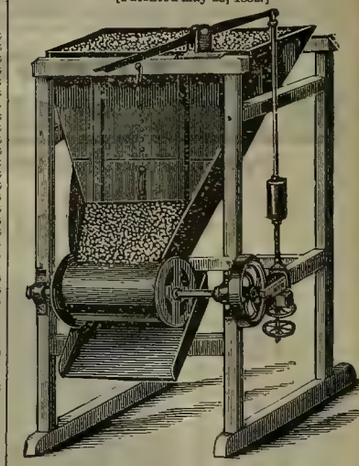
Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

YOUNG MINING ENGINEER WANTS A position; understands all works in gold and silver mines, mills and chlorination work; is good assayer and surveyor; speaks Spanish, English and German. Address MINING ENGINEER, 1408 Van Ness Ave., San Francisco.

THE ROLLER ORE FEEDER

[Patented May 28, 1882.]



THIS is the best and cheapest Ore Feeder now in use.

It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

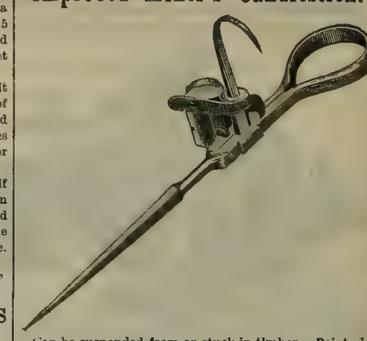
In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,

Sole Manufacturers,

827 First Street, San Francisco, Cal.

Improved Miner's Candlestick.



Can be suspended from or stuck in timber. Point detachable and folds in so candlestick can be carried in the pocket. Guard automatically extinguishes candle when short, to prevent accidents. Patent rights for Pacific Coast for sale.

GABRIEL WERNTZ,
Placerville, El Dorado Co., Cal.

—THE—
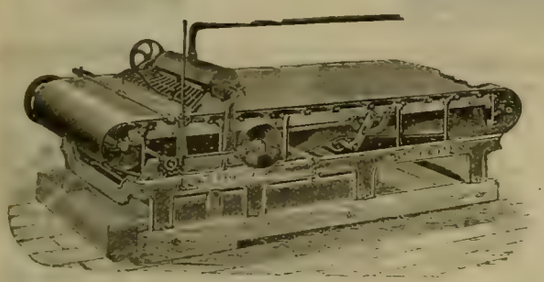
FRUE ORE CONCENTRATOR
OR VANNING MACHINE.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,
Room 15, No. 132 Market Street, - - - - - - - SAN FRANCISCO, CAL.

$1,000 CHALLENGE ACCEPTED,



PRICE, FIVE HUNDRED AND FIFTY DOLLARS
($550.00).

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

THE
"TRIUMPH" ORE CONCENTRATOR.

JOSHUA HENDY MACHINE WORKS,

New York Office, 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

VOLUME LVIII. Number 11.

The Santa Clara District.

We give on this page a sketch map of the new mining district in Lower California, showing the lines of travel to the mines from San Diego and Ensenada. The steamer is taken to Ensenada, fare $10; but overland the route from San Diego is by way of Tia Juana. The new gold mines in the Santa Clara region are about 60 miles from Ensenada. One route from Ensenada is via Las Animas and La Grulla up the La Grulla canyon to within six miles of the old Santa Clara ranch, where the trail leaves the wagon-road on the right and goes over to the camp about six miles distant. The other route is via Las Cruces, San Rafael valley, Los Alamos to Santa Clara ranch house, and thence by trail over to the mines, ten miles distant. Hay, grain and food can be had on the La Grulla route at Las Animas, 20 miles, and at La Grulla, 28 miles from Ensenada. On the northern route, hay, feed, and meals can be had at the Real del Castillo.

The mines are about 35 miles southeast of the Real del Castillo. Steps have been taken to open a wagon-road from the La Grulla and Santa Clara wagon-road over to the mines, six miles distant. There is plenty of wood, water and grass at and near the mines.

The canyon of the river or creek, Las Animas, is to the southward of Ensenada. Taking conveyance at Ensenada, the drive lies through the "city" of San Carlos, across the Manradero valley and up the Las Animas. La Grulla canyon enters Las Animas some miles from its mouth on the left-hand side. It costs from $20 to $25 per man to get from Ensenada to the mines.

Passengers for Tia Juana leave San Diego on the National City & Otay railroad, if they go overland. Teams, however, drive down there.

ROUTES TO THE LOWER CALIFORNIA MINES.

At Tia Juana is the Mexican custom-house, where clearance papers are signed. Burros and mares go in free, but horses are taxed $40 each. It is said there is not so much delay here as at first reported. Besides the duties, it costs $6 to pass the custom-house.

From San Diego to Tia Juana is 20 miles. A stage-line carries passengers for $25. The stage makes its three-night station in the 120 miles' journey at Murphys ranch in the Valley of Palms, at Ryerson's ranch, and at the Real, reaching the mines the following day. The roads appear to be pretty good, and are crowded with all sorts of vehicles. Many men are making the journey on foot. The map shows the line of the wagon-roads both from San Diego and Ensenada.

Mine Timbering.

The plan of mine timbering known as the Nevada system consists in filling the space exhausted in the ore body with a series of frame cubes. The drawings on this page will show the value of this system of timbering as related to strength, facility in erecting and its adaptability to all thicknesses of ore deposits or variations in hanging and foot walls. When the walls of the ore deposit are tolerably firm and not easily softened by exposure to the moist atmosphere of the mine, this system possesses great strength, but when the hanging-wall is of soft clay slate, softening rapidly on exposure, this system, with its large timbers, affords only temporary support. Collars and cross-braces are used to arrest a squeeze. The depth to which this system can be carried safely depends on the firmness of the hanging and foot walls more than on the increased pressure from depth. Some very large spaces have been filled on the Comstock with this system, and an immense amount of timber is annually used there.

Mexican Gold Mines.

A Prospecting Tour in Sonora, Mexico.

EDITORS PRESS:—We read sometimes, highly colored accounts of the hidden wealth and abandoned gold and silver mines of Sonora, Mexico, and it may interest some of your readers to obtain a plain and unvarnished account of a six-months' prospecting tour, during which some of the most renowned gold districts of that State were visited. It is only of gold regions, and by no means all of them, that this article will treat of the prospects in the Ures, Hermosillo and Montezuma districts, and along the San Miguel, Oposura and Yaqui rivers.

Some of these gold regions are over 30 miles long; others considerably smaller. In all these the canyons and creeks are auriferous, and a multitude of abandoned holes from which gravel, pay dirt was extracted, or in some places many arastras, testify to a former activity in those places. But it is not only in the canyons that gold is found; on some table-lands good prospects can be obtained, and were it possible to apply the hydraulic process, good returns could be obtained; but water is either scarce or ditches would be too costly to allow this kind of operations. In some districts quartz veins are more or less numerous, of which some are worked in a more or less slipshod manner with more or less benefit, or rather with more or less loss, with a few exceptions.

Mentioning the different districts in sequence as I visited or worked them one after the other, I have first to ask indulgence for occasional seemingly irrelevant remarks about the honesty, or rather absence of it, in many with whom I had to deal, foreigners as well as natives, well-to-do as well as common people; but these things are closely related to mining and prospecting operations in this country, and it may prove profitable, to some at least, to be posted in some details. Such experiences when read, noticed and considered by would-be investors are much cheaper than those acquired by one's own trials and investments.

Alluring indeed were the accounts which made me travel up and down the Sonora river. Near Baviacori was represented to be a very rich gold quartz mine, in which father, brother, cousins and other relations of the present proprietor are said to have been killed by Apaches, and thus prevented the present owner, an old man, pursuing further labor on the mine. I may observe in connection with this that such an Apache story is now regularly used and imposed upon would-be investigators. In every instance the miners took rich ore out of their claims, when they were surprised and nearly all killed by these Indians; generally one survivor escaped, who afterward covered up the shaft or tunnel, having had since no opportunity nor means to reopen the mine. For a consideration the aforesaid survivor is said to be willing to show the place and to sell his claim. To such an Apache story I was treated, and, thinking it worth while, I made the trip. In Baviacori we found the old man, who proved, as far as honesty is concerned, an exception to the general rule. Inquiring for the average yield of the quartz in an arastra, he confessed it was $9 per ton, the ledge three feet wide, and a small tunnel, an opening a few feet deep made; but he could not come along just now. The location was ten miles up in these rough and barren mountains, with neither road nor trail, nor had he mules to carry water along, as there was none nearer than nine miles. Concluding on the spot that I would not further trouble this excellent man, I mounted my horse, and wiser and tired, began the return march.

Shortly afterward an American living in Hermosillo pretended to have a good thing which he was willing to divide with some one who would open the mine, build a mill and advance him a few hundred *pesos*. A quartz ledge half a mile long, eight feet wide, running into a steep hill, well situated for tunneling, with wood and water in abundance, near a wagon-road, and averaging $60 per ton, free gold. Did this not seem too good to be true? So it was. And yet it was nearly true with one single yet important exception. Galena and pyrites of iron were in abundance; of gold, scarcely any. The feelings of the owner of this ledge were considerably ruffled, as is often the case, when I had to decline his generous offer. Shortly afterward an advertisement in a local paper offered this eight-foot $61 free-gold-per-ton ledge for sale—as if such a property needed advertising. Concluding to leave it to some Eastern or English capitalists, I went to the Yaqui River, near San Antonio de la Huerta, a rough mountainous country, where one meets in the gulches many abandoned gravel-holes. Another great and grand gold mine was offered, which on inspection proved to consist of an eight-foot deep hole in an apparent quartz vein of undefined size, no walls having been reached; the stuff was rotten quartz and oxide of iron and looked promising, and showed in the horn a few colors, seeing which the owner lost his head, so to say, for when I hinted that I might open the mine and eventually put up some machinery for half an interest, he felt indignant, saying there were English companies on the lookout for such brilliant prospects, offering large sums cash down. Well, I concluded not to interfere with his cash-down English companies. A few months afterward the same fellow offered me the whole thing for a song, but the offer was thankfully declined, as the water privilege in the canyon had in the meantime been taken up by other parties. This unprofitable experience cost me two weeks hardships, sleeping on the ground during that cold spell, with icicles on the blanket in the morning, sometimes no breakfast, and at all times poor fare, frijoles and tortillas.

In the Hermosillo district, some miles distant from the railroad station of Torres, is situated the Las Priestas mine and mill, of which mention was made in this paper; the shaft is over 600 feet deep, but the ledge has at last accounts not produced its usual quantity of good ore, so that the mill was run for more than a year on its tailings. *Quien sabe* where the fault lies and when it will pay again. The Las Prietas ledge, with its extension, is one of the most important mines in Sonora, yet in its neighborhood nothing of importance has yet been discovered.

From the Recorder of Mines of the district, as well as from some Americans, I learned of another important mine on the San Miguel river in Ures district. This Mina Santo Domingo was said to produce $35 quartz in an 80 foot shaft from a 20-foot ledge; good roads, wood and water, and yet the proprietors were poor and wanted to sell. On examination, it proved to be so, but again with the exception of the quality of the quartz. On the first day, prospecting with a proprietor, and letting him choose the samples, all was lovely, for good prospects were found in nearly every horn. On the second day, prospecting alone, things wore a different aspect; in short, the ore was found to average about one dollar per ton all through. The ledge contained some good-looking, yet poor, quartz, bunches of oxide of iron containing the gold, and at the bottom of the shaft solid barytspar. Such variations are often met in these ledges whenever they are opened to some depth; so was it with another mine in the same district, La Dorado, which was opened by a 100-foot shaft in a 30-foot orechute; ledge 10 feet wide, free gold on top. By sinking, some galena and carbonate of lead appeared, which increased in depth, while the gold decreased, and finally the whole thing will turn out to be a lead mine.

In the same district lies the "Cerro de Oro" (gold hill), an irregular cone some 700 feet high, clearly distinguished from surrounding mountains by its reddish color. This hill is traversed in all directions by small veins of quartz, some of them good ones, but invariably pinching out at little depth; only a few natives were making a precarious living there with an arastra.

A more important and inviting district lies south of Matape toward Santa Barbara and Sibachicory, west of the Oposura river, 30 to 40 miles in length. In nearly all canyons and on some flats, more or less—generally less—gold can be found. It was formerly a favorite resort of the Apaches, and this is the principal reason alleged why little work is done there. Numerous quartz veins are met with, as for instance, in La Bota, where quite a network of ledges can easily be traced; in some of these the color can be found on the surface; sinking 30 feet on two of the most promising ledges, no trace of gold could be found at the bottom. The formation is granite and porphyry.

In La Ramada, near Santa Barbara, some mining is yet going on, which consists in digging holes 10 or more feet in diameter and depth till pay gravel is met, which is then washed in a batea; some use blowers for dry-washing, as water is not abundant. When the gravel is extracted, another hole is dug; the gravel bed is about one foot thick, and the people make just their living (and a poor one in the bargain).

About 10 miles northwest of Santa Barbara lie the Amargoza and the Colorada mines, the latter the most important I have yet seen in Sonora. The Amargoza can scarcely be called a vein, but rather a large bunch, 20 or more feet wide, excavated to a depth of 30 or 40 feet, till the water could not be handled any longer. The ore contains galena, iron glance, copper pyrites and peacock copper ore. A few specimens show free gold and metallic copper joining—a rare occurrence; 110 arastras in the immediate neighborhood indicate lively times in former years. Crossing, or rather adjoining the Amargoza, is the Colorada la Reina, as far as can be seen over 12 feet wide and traceable on the surface for a few hundred feet, the ore of which consists of a clayey, rusty stuff mixed with decayed quartz, all containing free gold. It would be a splendid properity here in California, or even down there if well managed. It has a tolerably well-defined wall on one side, and lies in a talcose schist. In the hole of the adjoining Amargoza is met the only water for miles around, but it is bitter to the taste, hence the name Amargoza—bitter. The water acts as a laxative "till one gets used to it."

Near by is the Rosales group, a promising property consisting of several gold, silver and copper-bearing veins, two of them opened by a 100-foot shaft. There also is little and bad water. These mines are being developed now by a St. Louis company, the former owners not having succeeded in interesting Californians in these promising mines.

I might cite more names and descriptions of prospects and of ledges, of holes and of outcroppings, but *cui bono?* There is very little or no disposition evinced by Californians to invest in Sonora, and, judging by my own experience, they are not altogether to be blamed.

THEO. G. ED. WOLLEB.

Timber on Government Land.

The Other Side of the Situation at Eureka.

EDITORS PRESS:—In your issue of Feb. 23, 1889, I notice an article concerning the timber suits that have been instituted by the Government against certain mining companies in Eastern Nevada. Great stress seems to be placed upon the fact that Commissioner Stockslager refused to produce a certain letter written by Henry Rives, assistant counsel in the cases. Being somewhat familiar with a majority of the facts concerning these cases, I believe that the Commissioner has acted as any man of principle would or should act under the same circumstances; the letter referred to was one that was marked "personal and confidential," and was not an official letter, consequently Commissioner Stockslager could not under any circumstances have used the same unless he first obtained permission from the writer. Such permission was asked through telegram, but was refused on the grounds that no opportunity was given to the writer to sustain the position he had taken in said letter; but that if the Committee on Mines and Mining, who are making the investigation, would subpœna certain witnesses to sustain the writer, the Commissioner had full authority to use the same.

How could a more fair proposition be offered? Mr. Rives had stated certain things in his letter which could be proved by reliable and credible witnesses; but it seems that the committee would not allow him that privilege, and under those circumstances Mr. Rives was justified in not allowing said letter to be used. These timber cases are misunderstood by the general public, inasmuch as they have been led to believe that they were working a hardship to the mining enterprises of the country, but such is not the fact. Neither one of the companies shut down in Eureka had any intention of running through the winter months; in fact, they had all their arrangements made to shut down on the first of the year. The Richmond Mining Co. had on hand when the seizures were made 16 cords of cedar wood and about 2000 bushels of charcoal. The Eureka Con. had neither wood nor charcoal seized. That does not look as if either one of the companies intended to run very long. Considering, moreover, the fact that the worst part of the winter was near at hand, it would have been utterly impossible on account of bad roads to get further supplies in. The only case wherein a mining company could have been interfered with was in the case of the Sweetwater Mining Co. at Seligman, White Pine county, and in that case, the Deputy U. S. Marshal, who went there to make the seizure, did not seize any wood, on the ground that if he did, he would be interfering with the mining operations then being prosecuted. In all the cases so far brought by the Government wherein seizures have been made, the Marshal or deputies who made the same received written instructions not to seize when the Act would interfere with mining operations.

There are always two sides to a case, and although these cases may at first glance seem to work a hardship, it is really something that should have been attended to years ago.

The Richmond Mining Company, a foreign corporation, has denuded the public domain of hundreds of thousands of cords of wood for which they have never paid this Government one cent. They have even refused American citizens the right to pick up dead wood from off the ground for domestic purposes, when they had no more title to the land than any one else, never having purchased the same from the Government. Why should they not be made to pay for the same? Where on God's green earth could an American go and do the same act unless he was made to suffer for it? This investigation at Washington is a one-sided affair. No one outside of a special agent and Stockslager has been subpœnaed to testify on the part of the Government. Why not give both sides a fair and impartial hearing and sift the matter thoroughly? Then the U. S. Senate can act understandingly in the premises when the report of the committee is laid before them, but such does not seem to be the intent or desire of those interested in the matter; they desire to all intents and purposes to obtain only evidence that will benefit the defendants, and will not allow anything to be done or said that will be of benefit to the Government. Why, sirs, the joint resolution that was passed by the present Nevada Legislature was introduced in the Assembly by Mr. Cheney (of the law firm of Wren & Cheney), who is one of the regularly employed counsel for the defendants in these timber cases and a partner of ex-Congressman Wren, one of the principal witnesses for the defense at Washington, and it was introduced in the Senate by Mr. Comins of White Pine, who is representative or agent for two companies in White Pine county who have cut thousands and thousands of feet of lumber from off the public domain without having rendered to the Government its equivalent in cash, and who, no doubt, in course of time, unless Congress interferes in the matter, will be called to account by the Government for the cutting of the same.

I do not blame these gentlemen for their actions. It is an old saying, and a true one, that "a stitch in time saves nine," and if by any hook or crook they can have the suits discontinued, they and their clients will be so much the richer in the end.

I wonder what they intend doing with the E. & P. R. R. Company, who are also being sued. This company certainly has no right under the law to use the wood, railroads being especially prohibited from using the same. Now, Mr. Editor, I have the interests of Nevada as much at heart as any one of its citizens. It is my home, and I expect to remain here for years to come; but I do desire to see justice meted out to all concerned. If these companies have transgressed the laws of our country I believe they should be made to suffer for it, even if they are large and powerful corporations, and one of them an entirely foreign one at that. And on the other hand if they have not, I want to see their skirts cleared and be allowed to proceed with their workings, for things are now—in this section of the country—in a very unsatisfactory condition, although I am free to confess that I do not believe these timber cases have anything to do with the present state of affairs as they exist. I believe that the trouble arises from the fact that the Richmond and Eureka Con. Companies entered into a mutual agreement concerning the purchase and reduction of ore, which forced the miners to the wall, they demanding such an exorbitant price for working the same, etc., that all that would be left the poor miners would be the mountain air to live on. What Eureka county needs at present is new companies—such ones that will deal fair and squarely with the men who risk their lives in delving in the bowels of the earth, and who will give a fair price for ores and ask a reasonable rate for reducing same. When such a company commences operations in this camp, then will Eureka take its place again as one of the largest ore-producing camps in the country, and not until then, for the manner in which the present companies have been working it has been all one-sided, the companies getting everything, and the miners—in the common parlance of the day—"soup." THOS. PEABODY.

Eureka, Nev. March 1, 1889.

The Victor Concentrator.

EDITORS PRESS:—While in the mountains of El Dorado a few days ago I found myself at the plant of the Church Gold-Mining Co., three miles from Mud Springs. The owners are making extensive improvements in their hoisting works preparatory to sinking deeper on the vein, and everything about the plant betokens good ore and plenty of it. The rock at this mine is a brittle quartz lying in black talc-slate and is crushed in a ten-stamp battery, after which it is passed over concentrators to save the sulphurets, which are very light and fine. At the time I was there, the pulp from five stamps was run over two Frue vanners, while one Victor concentrator handled the pulp of the other five stamps.

Being familiar with concentrating machinery, it was a source of much satisfaction to me to witness the working of the latter machine which does so much apparently so well. The concentrates are discharged from a spout which leads from the center of the machine into a bucket, and, to the eye, seem absolutely pure, while I was assured by those in charge that there was no value whatever in the tailings. The millmen say that, other than oiling, no attention is required to operate the machine, a great advance in this class of machinery. This is the most compact and efficient concentrator I have yet seen. All the works of the mine except the hoist are operated by water-power under a pressure of 460 feet. X.

Mud Springs, March 8, 1889.

Sutro Tunnel Finances.

Receipts and Disbursements Since 1884.

Theodore Sutro, president of the Sutro Tunnel Co., furnishes the *Engineering and Mining Journal* with the following interesting figures, never before published, of the company's receipts and disbursements for the past five years:

	Receipts.	Disbursements.	Profits.
1884	$133 508 92	$ 95,652 55	$ 37,856 37
1885	193 280 25	80,085 50	113,194 84
1886	259,247 25	79 304 83	179,944 44
1887	271,343 47	98,414 53	172,808 94
1888	309,095 54	126,594 55	183,400 99

In commenting upon these figures Mr. Sutro said: "The increased disbursements in 1887 and 1888 were caused by extraordinary expenses connected with the foreclosure litigation; the reorganization and issue of new bonds and the work done for mining companies, for which we received compensation, of course, such as excavating the Chollar station and the Crown Point drift. It would be a safe estimate to say that the ordinary expenses for the past two years have not exceeded $84,000 per year. This year, 1889, there will be few extraordinary expenses. The total charge on the new bonds, of the face value of not quite $2,200,000, will be for the first year about $88,000, but as the bonds are redeemed, this amount will be steadily reduced. The receipts from royalties during January were $22,000." The stock is quiet at from 9 to 11 cents, but the business in the Trust certificates was large, and amounted to 54,500 shares, at prices ranging from 58 to 60 cents.

AN ABANDONED MINE PROVES VALUABLE.—There has been a rich strike made in the old Pack mine, about 35 miles south of Prescott, Arizona. The mine has lain idle for a long time and the owners have had for the last two months men in the mine clearing it out. A body of ore was struck in a tunnel and it is said to be equally as rich as any ever taken out of the mine. A big force of men will be put in the mine immediately and a lot more machinery ordered.

Mines on Railroad Lands.

Full Text of a Recent Decision.

Much comment has been excited by the Supreme Court decision in the case of Gale (plaintiff and respondent) vs. Best (defendant and appellant), in which the rights of miners have apparently been further curtailed. Appellant claimed certain land held by respondent as agricultural under a Central Pacific railroad patent to be mineral, and on that ground asserted his right to possession of it.

The decision, rendered by McFarland and concurred in by his confreres without exception, relates:

The rule is well settled by numerous decisions of the Supreme Court of the United States that when a law of Congress provides for the disposal and patenting of certain public lands upon the ascertainment of certain facts, the proper officers of the Land Department of the General Government have jurisdiction to inquire into and determine those facts; that the issuance of a patent is an official declaration that such facts have been found in favor of the patentee; and that in such a case the patent is conclusive in a court of law and cannot be attacked collaterally. Of course, if the patent be void upon its face, or if looking beyond the patent for a law upon which it is based, it is found that there is no law which authorizes such a patent under any state of facts, or, that the particular tract named in the patent has been absolutely reserved from disposal, then the patent would be worthless and assailable from any quarter. For instance, if a certain section of a certain township described by legal subdivisions should be expressly and unconditionally reserved by Congress from disposal under any statute, a patent for any part of such tract would be void. But if a large body of public lands be subjected to sale or other disposition under a law which has merely a general reservation of such parts of those lands as may be found to be of a particular character —such as swamp or mineral—then the Land Department has jurisdiction to determine the character of any part thereof, and a patent is conclusive evidence that such jurisdiction has been exercised. In such a case the patent could be attacked only by a direct proceeding, and by a person who connects himself directly with the title of the Government.

United States Supreme Court decisions in support of these views are cited, reference in particular being made to the cases of Smelting Co. vs. Kemp (104 U. S., 636,) and Steel vs. Smelting Co. (106 *Id.*, 447). The decision then proceeds:

It is contended by appellants that former decisions of this court, in McLaughlin vs. Powell (50 Cal., 64); Carr vs. Quigley (57 *Id.*, 394); and Chicago Q. M. Co. vs. Oliver (16 Pac Rep., 780), are in conflict with the doctrine above stated. Whether or not there be any expressions in the opinion in either of those cases inconsistent with the views of the highest Federal Court on the subject (which views, in the end, on a question like this must prevail), it is not necessary here to consider. In order to affirm the judgment in the case at bar, there is no necessity to upset either of those cases. In McLaughlin vs. Powell the patent itself excepted "all mineral lands, should any be found to exist in the tracts" embraced by the patent. And the decision is expressly put upon the ground that there was that exception, and that it was "part of the description" of the lands conveyed. And it may be strongly argued that, in such case, although it was the duty of the Land Department to determine the character of the land before the issuance of the patent, yet, as the patent shows upon its face that such duty was not performed, the patentee must be held to have taken it knowing its uncertain and unsubstantial character. On the other hand, Judge Sawyer has held, in an opinion of great force and ability, that the issuance of a patent in such a case was a conclusive declaration that the land was of the character to be properly patented under the law—that is, agricultural land; that there is no authority to make in such a patent a general reservation of mineral lands—any more than there is in case of a pre-emption patent; and that such a reservation is void. (10 Sawyer, U. S. C., 2 Rep., 8th Circuit, 246.) At all events, as in the case at bar the patent contains no reservation whatever, the case of McLaughlin vs. Powell is not authority here. And the same may be said of Chicago Q. M. Co. vs. Oliver. In that case the patent also excepted "all mineral lands, should any be found to exist," etc. Carr vs. Quigley is not in point at all. In that case there was no question about the character of the land patented. It was claimed to be within a "Government reservation;" and that the body of land itself involved in that case, without reference to its character, was expressly reserved from the operation of the law under which the attempt was made to patent it.

Our opinion is that where a patent issues for public land under a law which provides for its disposal as agricultural land—either to a railroad company or to pre-emption or homestead claimants—and there is no reservation in the law except a general one of mineral lands, and no reservation at all in the patent, then the patent must be considered as a conclusive determination by the Government that the land is agricultural; and afterward, in an action in a court of law, it is not competent to reopen the question of the character of the land. The opposite view would render the titles to a large region of California, now filling up with agricultural settlers, unstable, insecure and almost worthless. It would affect, also, those holding through patents under the pre-emption and homestead laws, for mineral lands are exempted from the provisions of those laws. The theory of that view is that if the land previously patented as agricultural can at any time be shown to be in fact mineral, then the title to it never passed from the United States, but had always remained a part of the public domain; and, as no statute of limitation runs against the Government, the insecurity of the title under the patent would be perpetual, and an attack upon it could be made as successfully 100 years hence as now.

The view taken of the question presented by the court below was correct, and we see no error in the record.

NEW RAILROAD AND REDUCTION WORKS.—Advices from Butte, M. T., state that Manager Law of the Montana Union railroad has returned from Omaha, where he went to confer with Union Pacific officials in regard to laying a double track and doubling the capacity of the present road. This will take an expenditure of $1,000,000. Anaconda City is to have new shops, a new depot and a new road laid with 75-pound steel rails from Silver Bow canyon to Anaconda, a distance of 11 miles. The new road is to be for freight and ore, while the old road is to be used for passenger service. The Anaconda Co. will commence at once the erection of immense lead and refining works. Manager Law has already ordered 20 new engines and 200 dump ore cars for the additional road.

THE NEW STATES.—Delegates to constitutional conventions in each of the proposed States of North Dakota, South Dakota, Montana and Washington, will be elected on the Tuesday after the first Monday in next May, and will meet to draft constitutions July 4th. Elections to ratify the constitutions thus agreed upon will be held on the first Tuesday in October, and when adopted it becomes the duty of the President by proclamation to admit the States formally into the Union. Each will be entitled to one member of the House of Representatives, except South Dakota, which will have two.

THE amount carried by the General Appropriation bills passed at this session of Congress is $281,879,000 against $306,986,000 appropriated for the current year.

Ensenada, Lower California.

We give on this page a view of the harbor and city of Ensenada, Lower California. This place has only been founded a few years, and is now coming into prominence as the point where the steamers from San Diego land passengers for the new mining-fields which are causing such an excitement in the southern part of the State. The steamer makes trips two or three times a week between this place and San Diego. From Ensenada the traveler goes overland by horse or mule to the new mines.

Ensenada is an American colony on land belonging to the International Company. It has attracted quite a population in the past year, but has now become almost deserted for the time being, owing to the mining excitement in the region back of it.

GENERAL VIEW OF THE HARBOR AND CITY OF ENSENADA, LOWER CALIFORNIA.

END OF A MINING SUIT.—In the case of Peter L. Kimberly against Chas. D. Arms and others, the United States Supreme Court has rendered a decision in favor of the plaintiff. The amount involved in the suit is $1,200,000. Kimberly claimed in substance that he sent Arms as his agent to Arizona on a prospecting tour and furnished the necessary funds, and that Arms located a number of valuable claims, which have since paid heavy dividends, and refused to make any accounting to him for any of the transactions. Arms denied that he was the agent of Kimberly, and claimed that whatever investments he made were with his own funds, and that Kimberly had no interest in them. Arms is in affluent circumstances and recently completed the finest residence in Youngstown, Ohio, at a cost of over $100,000.

HORSESHOEING BY ELECTRICITY.—A novel use of electricity is about to be tested in sharpening the shoes of car horses in icy weather without removing them from the stable. This important application of electricity is being made by the Baxter Electric Manufacturing Company of Baltimore, and is likely to prove one of the most useful applications yet made of this subtle force, and will especially commend itself to the Society for the Prevention of Cruelty to Animals.

THE COINAGE OF SILVER.—Senator Stewart says he intends to test the sense of the Senate on his silver resolution at the first opportunity. He appreciates the fact that no legislation can be enacted during a special session, but his resolution is in the nature of an instruction or suggestion to the Secretary of the Treasury. Under the law he has discretion to act on the suggestion without any other legislation.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

NORTH STAR.—Amador *Dispatch*, March 9: At this mine they have commenced to drift north from the hanging-wall. The tunnel running south is now 280 feet from the shaft. The work in this last tunnel has been temporarily suspended, but will be resumed as soon as the tunnel running north gets in far enough so as to prevent blasting from interfering with the south tunnel air-pipe. It is claimed by old miners that the south tunnel will strike the chimney when in about 100 feet more, as the surface indications at that point are considered good.

MORLEY.—Hearing so much of this mine, and the 20-stamp mill to be erected thereon, we concluded to pay a visit to the place last Sunday, and were very much disappointed at the outlook. From present indications there has been no work done lately, and we were informed that what work had been done revealed only a few small stringers. We were unable to find any ore on the dump, and all the quartz we saw consisted of croppings which could be traced a hundred feet or so. It seems to us absurd to think of erecting a 20-stamp mill there. On our way down we passed two mills, one of them within 300 yards of the Morley property, both of which are going to rack, and we are told they were erected on prospects far brighter than the Morley. This thing of building mills for speculative purposes is only a drawback to the mining interests of the county.

AMADOR GOLD MINE.—Work is going steadily on this mine. Several improvements have been put on the property of late. The new Kendall one-stamp mill is about completed. With this little mill they can make a milling test of the ore at any time. The large mill is also nearly ready for operating; the stamps are all in position, but the concentrators are not yet set, nor the belting put in place. The new assay office is neat and handy,

ALPI.—W. T. Robinson, J. E. Hagerman and E. F. Henderson were awarded the contract for sinking the shaft at this mine 50 feet below the tunnel level. The contract price was $4.75 per foot, contractors to furnish powder, caps, candles and fuse. A station is being cut at the tunnel level. How the company expects to utilize the tunnel with a hoist on the surface, we are at a loss to know.

DRYTOWN CON. — The company is pushing work. The ditch has been cleaned out to the Gover mill; the cut for the pipe has been dug up China street, and the pipe is being laid as fast as possible. The shaft has been cleaned out down to the water, and found in good order.

COSMOPOLITAN.—Work has been resumed on the 500-foot level. The station has been finished at the 300-foot level. The new boiler has been set, and the brick-work completed; it will be connected to the engine in a few days.

NORTH CALIFORNIA.—The mill is running again, after a few days idleness. The cleanup for last month was beyond expectation. The Gover mill has started again on very good ore.

WILDMAN.—This mine is looking well. They have a fine ledge of $5 rock at the 100-foot level. The mine paid $1000 over expenses in January, and did about as well last month.

PLYMOUTH CON.—About 50 men are at work at this mine, and more men are being put on every few days. The mill is running 40 stamps; the other 40 will start up soon.

Calaveras.

GOLDEN EAGLE.—Calaveras *Chronicle*, March 9: The Golden Eagle mine is situated near the Lockwood in the West Point district, and is owned by G. W. Moore and William, Eugene and Elmer Holbrook. The shaft on the mine is 70 feet in depth, at the bottom of which a drift has been run north 90 feet. The vein averages from 20 inches to two feet in width. Six tons of unassorted rock from this mine, crushed in the Blazing Star mill, yielded at the rate of $20 a ton free gold, and about 1000 pounds of sulphurets that assayed at the rate of $150 a ton. The natural facilities for working the mine are excellent, and we understand it is the intention of the owners to erect suitable machinery for the further development of the mine.

THE UTICA MINE is running in full blast day and night. The large 60-stamp mill, with all its modern appliances for saving the gold and sulphurets, is kept in constant motion. Work is going on actively in the stopes of the south shaft, while sinking is carried on with a vim in the north shaft. A vein of high-grade ore, we are informed, and some of it immensely rich, has been tapped in the south shaft. The rock is said to be superior to any taken out of this mine in many days. As nearly as we could learn, the Utica is surpassing the expectations of its owners as a gold-producer.

OTHER MINES in this section are being worked energetically, while there are others preparing to begin operations on an extensive scale. The Tulloch & Lane mine, situated a short distance south of this town, is in constant operation and yielding good returns. The Calaveras mine, situated at Robinson's Ferry, is being put in shape for operations on a large scale.

THE ANGELS MINE is being worked day and night, and is making an excellent showing. The ore now being mined is said to be of a good milling grade, and there is an immense body of it in sight.

El Dorado.

PAY GRAVEL.—Georgetown *Gazette*, March 7: The Kentucky Flat tunnel, belonging to A. J. Wilton, is in 650 feet at a depth of 100 feet. An upraise of 18 feet in face of tunnel opens up a bed of gray and blue pay gravel from three to five feet in thickness.

THE LAST CHANCE MINING CO., under Supt. E. C. Cheek, has put a force of men at work on their mine adjoining the Whiteside or Crane's Gulch mine. They are now digging a ditch for conveying water to the mine. Extensive and ample preparations will be energetically carried on and the mine put in good shape for systematic and economic working by sluicing process. This mine cannot fail to yield up handsome returns under the present plans of working.

Inyo.

AROUND KEELER.—*Reporter*, March 9: Eight experienced Italian marble-cutters are now at work at the marble works, and the indications are that enterprise will assume large proportions in a very few months. The soda works on the lake have lately been improved by large additions to the reduction machinery and appliances. Among the additions is the refining plant, which is now in active operation and doing finely. The approach of warm weather will close this part of the work down, as a certain degree of cold is essential in this process. A large furnace for making soda-ash will then be erected, and altogether the prospect is that these soda works will soon be the most extensive not only in this country, but in the world.

Mariposa.

HITE MINE SHUT DOWN.—*News*, March 9: The celebrated Hite mine at Hite's Cove was shut down last week by the men refusing to work. Judge Walker, who had it bonded, was behind with the men from two months up and in amounts ranging from $120 to about $850. Walker is behind about $20,000 in this county. He is now in the city and has written to most of his creditors that he is trying to get the cash to pay them. It is a public calamity to shut down this mine, especially when those in position to know say it has paid and can be made to pay.

COULTERVILLE.—The Red Cloud is being pumped out again, and work will be resumed at once. The death of Seth Cook makes the change of the Cook mines here one of the possibilities of the near future.

WHITLOCKS.—The contract of sinking the shaft on the Gerove & Ellingham mine was completed last week. The rock on the bottom looks well.

GRANITE SPRINGS.—Mariposa *Gazette*, March 9: The Mignonette mine is temporarily idle. It is reported that A. Rihn and others are taking out some very rich ore from a ledge on the ranch of the former.

KENDALL.—The Kendall claim on the Cathey's valley mountain, owned by Dr. Turner, was lately sold to Alex Rattray and Charles Anderson, for $750. This is a good mine for a small capital to work.

Nevada.

METROPOLITAN MINE.—*Tidings*, March 7: News from the Metropolitan mine, owned by "Happy George" Abram and situated near Moor's-Flat, is to the effect that the character of the ore has improved since the late visit of Capt. Stocks and D. McKay of this city. The ledge is somewhat smaller. Ore now being extracted will mill from $20 to $30 a ton. Four companies are negotiating for the property, but Abram does not care much about selling for a month or two, by which time he expects to cut his cross ledge.

Placer.

AT WORK.—Placer *Herald*, March 9: Fred Randall, who owns about 120 acres of good mining land east of town, along the American river, is hard at work on his claim. He has run a tunnel of some length which has developed a fine body of gravel, and the indications are very flattering that Fred will strike it rich. The gold already taken out is of high grade.

GOLD.—Placer *Republican*, March 6: The second cleanup at the Hathaway mine near Ophir was made last Friday after a run of 24 days. The yield was about 16 pounds of gold. Ophir people hope that this success will be the cause of new activity in the other quartz mines of that vicinity.

Plumas.

NEW MINING OPERATION.—Greenville *Bulletin*, March 6: From C. H. Lee, who arrived in Greenville Monday, we learn that he and several others have formed a company to turn the North Fork out of its present channel and work about one-half mile of the river bed. A short distance below the Glazier mine a large wing dam will be put in to turn the river into a slough. Much work will be required, but the enterprise is considered quite practicable.

Sierra.

RUBY MINE.—*Mountain Messenger*, March 9: Under the able management of Supt. John Co'man, the mine is prospering. It gives employment to 35 men. Ten new cars have lately been added. Forest City men are well represented here.

THE RAINBOW QUARTZ CO. of Chips Flat is reported to have at last found the true Rainbow ledge in their tunnel. The claim at Happy hollow, of which J. H. Frissell is superintendent, is paying nicely. This will give Port Wine quite a boom. Pearson's ranch and gravel mine at St. Charles hill has been sold for $15,000, it is said. The yield of the Young America mine for the short month of February was about $24,000.

THE BALD MT. EX. new main tunnel was in last Saturday night 2508 feet. The rock at the face is soft, black slate, easily picked and no blasting needed. Thirty-six feet were made last week.

QUARTZ.—A find of some very rich quartz is reported in the quartz ledge near Alleghany, formerly owned by Theodore Smith, now the property of Charles Heintzen of Forest City.

RIFFLE.—The Riffle Co.'s drift claim, above Port Wine, is paying handsomely. It is owned principally by the Prosser family.

DAYTON CON.—Sierra *Tribune*, March 8: The Dayton Consolidated is a short distance above the Salinas and Mercer and about six miles from Sierra City. It is owned principally by Grass Valley parties. Some time ago a contract was let to Messrs. Hammill & Johns to run the tunnel ahead 200 feet, making it in all 269 feet in length. This was done for the purpose of tapping the ledge which stands out in prominence on the surface top. According to their expectations a fine-looking ledge was opened up just at the finishing of the contract. The ledge is fully two and one-half feet wide and increases in size as it is entered in upon. Free gold can be seen in considerable of the rock. Frank Roberts, general manager for the company, arrived here Sunday night from Grass Valley to see about having further work done at the mine. Mr. Roberts informed us that the company will probably lease the mine to Messrs. Hammill & Johns, so that it may be opened up and further developments made. These two gentlemen feel sanguine that the ledge encountered is a good one.

THE SACRED MOUNT MINE is gaining a good reputation. The men who have the 200-foot contract are pushing the tunnel ahead rapidly. A good-looking ledge was encountered. The rock is filled with sulphurets and gold can be seen in some of it. Nearly all of it prospects well. The cleanup of the Sierra Buttes Mining Company for the month of February is $20,000. This storm, if it will only keep on for a few days, will give the Salinas & Mercer Mining Co. water to start their mill running.

BUFFALO.—Messrs. Frank Cook and Dr. Tully visited the Buffalo mine Wednesday. They brought down quite a number of pieces of nice-looking rock taken from different parts of the mine. All of it showed free gold.

Shasta.

KLINE'S GULCH QUARTZ MINES. — Cor. Shasta *Courier*, March 9: A brighter era is dawning on old Shasta, for it is now basking in the golden sunshine of success; at least such can be said of this favored part. When your correspondent got to French Gulch last Saturday, Harrison Fox and Tom Baker were running a free hotel for awhile; the cause was a rich strike in their mine adjoining Wheeler's claims. At a depth of 140 feet they cut a four-foot ledge that bristled all over with coarse gold. Fox says it will mill $100 per ton; Baker says $60. Frank Wheeler struck a new ledge which mills higher than any heretofore found in the claims. J. L. Carson is working steadily on his two 10-foot ledges, one of which shows free gold all over the face of the opening. The Gladstone mill and mines are being worked by a force of 16 men. They have just finished milling the old dumps that were extracted while prospecting the mines, which paid handsome dividends. Now they have reached a greater depth, the ledge is more compact and solid. Coarse gold can be seen in every piece of ore coming out of the double compartment shaft which is being sunk from the tunnel level. The ledge here is four feet wide. They are building a road and ore chutes on the Helena mine, in which gold is visible all through the rock. There are now eight locations on the Kline gulch lead adjoining each other in a straight line, any single one of which is a bonanza. There is no reason why more mines could not be found between the Gladstone and Squaw creek, for the ledge can be seen cropping out where it crosses the ridges. In the distance of six miles gold has been found in several places along its course.

GOVERNMENT PATENTS.—A sale of good mining property was declared off this week on account of there being no Government patent, and last week a sale failed to be made in French Gulch district for a similar reason. Fox, Johnson and Tom Baker of French Gulch district have tapped the ledge on the Gray Eagle claim 90 feet below the surface, and by a 140-foot tunnel. The quartz is of the free gold variety.

PROSPECTING.—Prospecting for quartz and pocket mines was never more lively in this vicinity and north of here than at present, and in many instances the prospector is not unrewarded.

Siskiyou.

SAWYERS BAR.—Cor. Yreka *Union*, March 9: The Gold Ball mine is in full blast, and 4 stamps running in the mill. The Uncle Sam mill has been hung up since last season, there being no water to run with. The Independence Co. are opening up the claim and getting ready for work. The owners are very happy over the prospects of a large fortune the coming summer. The Gold Hill is all rigged up ready for use.

San Bernardino.

THE GOLDEN BAR. — Redlands *Citrograph*, March 9: The Golden Bar M. & M. Co. has been organized with a capital stock of $300,000 and the following directors: B. F. Watrous, San Bernardino; H. L. Martin, San Bernardino; H. A. Nelson, Carlsbad, San Diego county; J. T. Colliver, San Bernardino; Jas. S. Robinson, San Bernardino. The mines are in the Yucaipa, some eight miles east of Redlands. There has been a great deal of prospecting done in days long gone by, but that was at a time when the cost of hauling rock to where it could be worked—unless the crude arastra process was sufficient—was $50 to $60 per ton, and when provisions were high and labor commanded a big price. Under these conditions ore that would not run considerable more than $100 to the ton was "no good." Now that these conditions have materially changed for the better, these old claims are being hunted up and relocated. It is the intention of the company to immediately proceed to open up their property and thoroughly develop it. They will also put up a small mill during the exploitation, to be succeeded by a larger one should the ledge prove to hold out as well as they expect. That there is gold in this Yucaipa region has been known for many years. Owing to the difficulties mentioned above, it has been supposed that the mines would not pay. It is now proving that they will pay, and pay well.

Trinity.

GOOD PROSPECTS.—*Journal*, March 9: S. J. Hensley returned from New River last week and says that the prospects of a lively summer in that camp are good. The mines are improving and a large force of men is at work.

EAST FORK.—From George Bailey we learn that East Fork is moving along as a new mining camp should. Work on the Yellowstone is progressing and all arrangements are being made for a mill which will be put up as soon as the wagon-road is completed. Bailey, Zuello, Nichol & Co. have run a tunnel on the Alaska 105 feet and expect to tap the ledge in about 15 feet more, at a depth of about 160 feet. Should the ledge prove as good at that depth as it is on the surface it will be a bonanza. Wagner & Trask have made a new strike just above the Yellowstone that shows very well, and is thought to be an extension on that ledge. The North Star is showing well and it is thought to be one of the best mines in the county. The miners are all at work and the summer will see the camp lively and many men employed. As soon as the wagon-road is completed there will be a chance for a more rapid development in the camp by getting a milling test of all ore, and assays of specimens will no longer be in order, but every ledge will come down to its merits; and we believe a working test will be a great advantage to the district, as it has nothing to fear from such a test.

Tuolumne.

MILLING VEIN.—Tuolumne *Independent*, March 9: At Brown's Flat, John Wainwright is sinking a new shaft on what was formerly known as the Dr. Franklin lode. It is a milling vein—and strange to say, is supposed to be the only milling vein in that section. Some 25 or 30 years ago some rich ore was taken from this vein, and the claim has not been operated since. Two years ago the lode was relocated by Mr. Wainwright, and he is now proceeding to develop it, and expects in a short time to prove the value of the property. He is sanguine he has a good thing. The Bonanza is at it again. In the last three days they have taken out about $28,000, and the end is not yet. Up to Thursday night they have taken out of this pocket, $110,000. Gold still in sight and mill still running.

NEVADA.

Washoe District.

YELLOW JACKET.—Virginia *Enterprise*, March 9: Explorations are in progress on all the levels from the 360 down to 900. Some good ore is being found on the 360 level.

HALE AND NORCROSS.—The vein continues to look well in all parts. The ore extracted is coming from the stopes on the 400, 500 and 600 levels. On all these levels a good deal of prospecting is being done. The company has $68,500 on the February bullion account.

CON. CAL. AND VIRGINIA.—Ore is being extracted on all the levels from the 1400 to the 1950. The 1600 level is that which shows the most and best ore. The shipments to the river-mills continue about the same, and the average of the pulp assays will be about as usual.

OCCIDENTAL.—Ore is still being extracted from the 300 and 350 levels. Quartz showing some metal is being found on the 450 and 650 levels. A new 20-stamp mill is being built by the company. The mill will be provided with concentrating machinery.

CHALLENGE.—Are shipping over 150 tons of ore a week to the Brunswick mill. The average assay is $21 a ton. A large amount of prospecting is being done on the 300, 1100 and 1300 levels. Most of the exploring drifts are in favorable vein material.

BEST AND BELCHER.—Prospecting is vigorously prosecuted on the 350 and 400 levels. On both levels quartz carrying some metal is being found. In all the openings the quartz found is of a fine and fertile appearance.

SAVAGE.—Are shipping nearly 500 tons a week to the Rock Point mill at Dayton. It averages $22.18 a ton. This ore comes from the 400, 500 and 600 levels, all the stopes on which continue to look well.

BELCHER.—The north drift on the 200 level has been connected with the 160 drift. Also the 1100 winze has been connected with the 1300 raise. Both are important connections in several respects.

CONFIDENCE.—Large shipments of ore continue to be made to the Brunswick mill. It averages over $21 a ton. The prospecting work joint with Challenge is showing favorable material.

POTOSI.—The mine is yielding over 800 tons of ore a week. The average assay is $21.50 a ton. The ore-producing sections continue to look well.

CON. IMPERIAL.—A considerable amount of prospecting is being done on the 1100 level. Also some repairing work is in progress.

NORTH OCCIDENTAL.—Good ore is being taken from raise above the 400 level. On the 250 level the prospects are good in the north drift.

SEG. BELCHER.—Connection has been made between the 1100 winze and the 1300 raise. It gives a fine circulation of air.

JUSTICE.—The mine is looking well and the mill is kept running steadily. It crushes 30 tons of ore a day.

UNION CON.—The north lateral drift is making good progress in ground of a favorable character.

UTAH.—The drifts north and south on the 600 level are still in a formation of clay and quartz.

SIERRA NEVADA.—Fair prospects are being found in the drifts on the 520 level.

BULLION.—Nothing new in explorations on the 500 level and in sinking below the 600.

ANDES.—Good progress is making in repairing and extending drifts on the 175 level.

OVERMAN.—The mine is sending about 280 tons of ore a week to the Vivian mill.

ALTA.—Continue crushing and concentrating daily about 30 tons of ore.

BALTIMORE.—Some high-grade ore is being extracted from the 225 level.

CROWN POINT.—Shipped over 600 tons of ore last week to the Mexican mill.

MEXICAN.—West crosscut No. 1 is cutting quartz of a promising character.

GOULD AND CURRY.—Work of repairing south shaft is still in progress.

OPHIR.—The ore in the upraise above the 1465 level is looking well.

SCORPION.—The crosscut on the 300 level is making fair headway.

SILVER HILL.—Still repairing the shaft timbering below the 400 level.

NEW YORK CON.—Still reopening the 300 level north drift.

Morey District.

AT WORK.—Belmont *Courier*, March 9: The work of development is prosecuted as usual in the mines at Morey.

Spanish Belt District.

BARCELONA.—Belmont *Courier*, March 9: The new stone mill at the Barcelona mine, Spanish Belt, is completed, and started up on ore from the dump Feb. 27th. The mill is equipped with a six-foot Huntington mill 30 tons capacity, rock-breaker, ore-feeder and six concentrating tables. The mine is looking well and producing good milling ore, with plenty of concentrating ore in sight. The Monitor-Belmont mill is still producing bullion. Since last November it has produced 58 bars; total weight, 71,890 ounces, all from Barcelona ore. The lessee, J. E. Severance, thinks without a doubt, with the aid of the new concentrating plant, he will be able to make a long and successful run the present year.

Reese River District.

DOWN TO THE BOTTOM.—*Reveille*, March 8: The Plymouth shaft has been timbered down to the bottom, a distance of 400 feet, and by to-morrow it

will be cleaned out and put in readiness for sinking. To-day the men on this morning's shift found a few drills, which they sent up to the surface in the bucket. They have been hoisting water in the bucket for about a week. W. H. Judson had the contract for fitting the sets and cribbing, employing Wm. Yeager to assist him. He is now an old hand at the business.

Silver Star District.

MILL FINISHED.—The completion of the stamp-mill for the Occidental company will be followed by an increase of nearly $50,000 per month in the bullion yield of the lode. There is a large area of ore stripped in the mine which shows an average assay value of above $31 per ton. There is a strong probability that the North Occidental and St. John, in the same district as the Occidental, will be added to the list of Comstock bullion-producing mines before next fall.

Tuscarora District.

BELLE ISLE.—*Times-Review*, March 8: The west crosscut from north drift, 250-foot level, has been extended 22 feet.

COMMONWEALTH.—100-foot level: No. 1 west crosscut from south drift has been extended 18 feet, showing good ore in the face. South drift from No. 1 west crosscut has been extended 16 feet, showing some high-grade ore. 300-foot level: The south drift from No. 1 west crosscut has been extended 12 feet, the ore improving in quality as the drift advances.

NEVADA QUEEN.—The north end stopes do not look quite so well; all the rest continue about the same. Average assay of concentrating ore hoisted during the week, $28 per ton. The concentrating works are running steadily and doing good work. The ore-chutes at the mill are being put up as fast as possible.

FOUND TREASURE.—Everything in and about the mine is in good order, and work can be resumed at a moment's notice. The steam pump now being used is capable to handle the water another 100 feet.

NORTH BELLE ISLE.—The stopes above the 300-foot level continue in ore. During the week the station timbers on the 300-foot level have been renewed.

GRAND PRIZE.—Face of south drift has been advanced 14 feet; vein four feet wide, carrying bunches of good ore. An east crosscut from the south drift has been started near the face, and is in 17 feet.

COMBINATION SHAFT.—The rock in the bottom is looking very favorable for ore.

NAVAJO.—The stopes are looking well and have yielded the usual quantity of ore.

Tybo District.

DIMICK.—Belmont *Courier*, March 9: From J. B. Gilmore we learn that there are ten men working in the Dimick mine at Tybo.

LOWER CALIFORNIA.

LATE DIRECT NEWS. — Cor. San Diego *Sun*, March 8: The latest direct news from the mines is contained in a letter written by I. E. Bennett, the Lower California correspondent. He says: American gulch, a branch of Mexican gulch, and widening at the head into a wide mesa, bears indications of still greater richness than the little gulch where work is now being done. By the time you receive this a string of locations will be made along the seam, which is quite large, and good developments are expected. The head of American gulch is bounded by high hills, and in these, especially Gold hill, most of the locations of quartz ledges have been made. L. H. Gaskill, Chas. Bennett, John Vipon and others have been exploring this region, and both Mr. Gaskill and Mr. Bennett tell me that indications point to richer developments than have been made anywhere for years. The Centipede lead which passes through the center of Gold hill is about 12 feet wide, and specimens pulverized in a mortar yield at the rate of $300 to $500 per ton. No quicksilver was used, but only a gold pan, so that much of the fine gold was lost. A close assay would doubtless show an average of $500 per ton. The Centipede, in Mr. Gaskill's opinion, is the mother vein of the district, as its length already discovered—eight miles—and richness would seem to indicate. The ledge is composed of rose quartz with an iron stain. Mr. Gaskill and his company have also located and denounced six other ledges, as follows: Mescal, one mile north of the Centipede; Bonita, on Burro hill, adjoining American gulch; Oro Fino, on Gold hill; Gold Queen and Cholla, both at the head of American gulch. Several more locations have been made by the same parties, and other ledges have been located by a company of ten organized last Tuesday in Ensenada. There is no doubt but that Santa Clara will in the end be known for the wonderful richness of its quartz mines, rather than of the placers, for though the latter are rich, the question of water will, in another month, be a serious one, and only choice locations will have a sufficient supply. The water will probably hold out till the middle of April, and in the interval we may expect to hear of big strikes being made. As was to be expected, good locations for quartz-mills, where ore, water and timber are accessible, are scarce, and in many cases will cost a high figure. Owing to misinformation as to the trail from La Grulla to the camp, a number of teams were compelled to stop about five miles down the canyon, being unable to push through. Those who came in via Real del Castillo and the Santa Clara ranch arrived all right, though the road is fearfully rough. Many Mexicans have brought their wives and families, and intend to stay here till they make their pile. The camp is strung along Mexican gulch for two miles, the Mexicans occupying the head of the gulch and most of the Americans clustering at the foot. The whole district presents a busy scene, and work is going on in all directions. Gold is found in every pan and enthusiasm in every camp. No one is to presume that all are getting rich "hand over fist," striking pockets at every blow of the pick, etc., or that this differs from the ordinary mining camp. On the contrary, many are barely paying their grub, and occasionally an unfortunate argonaut is encountered who came here on great expectations, and who is compelled to apply to his fellow-miners for rations. But these are exceptional; the majority are making good wages, and $25 to $100 a day is not uncommon. As was remarked by Chas. Bennett, the richness of the diggings is so wonderful that the average prospector, if he does not find nuggets in his panful throws it away in disgust, not stopping to wash out the fine gold. All gold taken out here is very coarse in size, from a pea to an inch in diameter. Color has been found in every gulch so far prospected, and even on the hills, near a ledge, a panful yielded ten cents of fine gold. There is room here for a thousand prospectors, and it would take that number of men three months to prospect this district. Six miles to the southeast of Alamo butte, which is the base of all measurements here, the Lopez brothers are opening a ledge of promising ore. There are several fine locations for millsites near their mine, with water (temporary) in the adjacent canyon. The extent of the district is wonderful, and it all promises equally well. If half is realized which now appears on the surface, this district will excel anything discovered since 1849. A healthy sign is found in the way the veteran prospectors are sticking to this country. They do not say much, but their silence speaks. A word to new-comers: Let all bummers and gamblers stay away. The police is well organized in this camp, perfect order is maintained, and no lawless claim-jumping or other customary mining-camp antics will be tolerated. All peaceable prospectors, willing to work, will find a welcome and plenty of room and material. All outfitting should be done in Ensenada or San Diego, as grub and tools cannot be obtained here. Fresh beef can be had, however, at 25 cents a pound, and an enterprising Mexican has established a portable blacksmith shop. Now is the time to come if work in the placers is contemplated. As I write, reports come in of rich quartz finds near the Lopez mines, and this afternoon four parties in Mexican gulch took out over $200, one nugget weighing $28. Several pockets have been struck during the day, but it is difficult to ascertain the amount, as the boys are not quick to give away their affairs. It is sufficient to say that this is the most promising gold-field on the coast.

THE NEW PLACERS.—San Diego *Sun*, March 9: H. H. McAllister writes from Ensenada on the 3d to C. H. Olinger that a great many of the rumors are exaggerations. "It is true," he continues, "that a great deal of gold has been taken out and that more yet remains. Mexicans and Indians are the most fortunate. An estimation places the amount of gold taken out at between $10,000 and $12,000. Every one there is not getting rich by any means. Some work all day and get nothing while a man ten feet away gets a pound. The opinion of several old prospectors with whom I have talked is that the placers will not last long, as they are very shallow, being not more than three feet deep. The belt is said to be several miles long, but only a small portion has been prospected. Water is not expected to last longer than the 1st of May. The quartz in the vicinity is well spoken of; it is a rose color and shows free gold. The nearest timber is about 50 miles from the mines. This is the pine region which extends very far to the southward. It is not a good variety for manufacturing purposes, as the limbs begin from the ground, making it very knotty. The root of them is good. I am referring now to the Hanson ranch and Camp National district. The trees are very tall and from two to three feet in diameter. All who could get away from here have gone out. I would not advise any one to stay away nor to go. A trip to the camp would do no harm."

AN UNLUCKY MINER.—Lesseps Story, brother of Hampton Story, writes under date of the 3d from the survey camp of the Martier engineering party on the Peninsula Air Line: "I have just returned from the gold mines, having staid there two days prospecting and working like a Trojan for gold. But a 'divil-a-bit I got.' As I wrote before, I thought the accounts were exaggerated, and so they are. So far I think about $2000 to $3000 has been taken out. The claim I took up was not worth a cent. Washing and digging for two days, I managed only to get colors. Dr. Allen of the International Co. is out there and he says that six miles from the placers rich quartz has been discovered. No doubt gold is around in large quantities. It would be well if you can manage it to provision for a month and shoot down this way to go prospecting. The mines are 15 miles from where we are camped. Captain Friend is out there reporting for the *Union-Bee*. I left him yesterday afternoon going to his camp to hatch up, as he said, a glorious account of the gold discovery and very little gold he saw. I suppose the people of San Diego are waiting anxiously for reports. It will be a good thing for the International Co. if true."

ANOTHER CORROBORATION of the gold find comes from Ensenada in a letter from H. H. Keeler to John A. C. Snyder, commission merchant, at 346 Fifth street. He says: "I saw one man who had $55 in gold that he took out in one day. He stated that the people are just running about, and if they cannot find much in one dig they go on. It is so easy to get, they don't stop to dig much. Provisions are very high and seem very scarce. People are crowding in here by the hundreds, and I heard from the camp to-night that things are getting richer and richer."

SANTA CLARA DISTRICT. — San Diego *Sun*, March 9: Interest in the gold-fields will be increased by the statement which comes from Dr. Garcia de Leon of this city. He is authority for the announcement that the mineral region about 45 miles southeast of Santa Clara is to be opened up by himself and Castro de Beraza, a colonel of the Mexican army, backed by the Mexican treasury. Improved mining machinery, mills and reduction works will be put in and a railroad will be built to a connection with the Ensenada road. San Diego is to be the headquarters of the company. Senor Beraza, who secured the concession for the Valledares mining territory, which is not a great distance from the new company's location, is now in the City of Mexico. Under date of Feb. 21st, he writes to the doctor that his mission had been successful. Dr. de Leon knows every foot of the peninsula. He is a member of the Medical Geographical Society of Mexico. As its representative he traveled over the territory from August 1886 to June 1887, and a year ago he made his report. His account of the mineral value of the lands was exactly what he says to-day, that the peninsula is rich in precious ores beyond belief. The doctor made locations in the Arroyo de Santa Gertrudez and on the ex-mission of San Borja. He brought back with him nuggets of great richness, but could get no one to believe with him that the great mines of the near future would be found there. Now it appears that the Mexican Government had become convinced of the value of Lower California minerals before the Santa Clara find was made. The territory that de Leon and Beraza propose to open is 60 miles long by 10 wide. A special method for reducing ores, which de Leon learned at the mining school in the City of Mexico, will be employed. He says that by this treatment color can be made to yield $60 to the ton, and that as high as $20,000 a ton may be realized with the high-grade ores. Operations will be begun in April. The doctor says there is no humbug about the Santa Clara district, it is very rich, but that people must work with some intelligence and method if they expect to gain anything. "I would," he concluded, "most certainly advise people to go to the mines."

DAKOTA.

REDUCTION WORKS.—Deadwood *Pioneer*, March 8: The embers have ceased to smolder, and the furnace for roasting what sulphides were saved from the wreck has been completed. Roasting began yesterday morning. When completed the sulphides will be shipped to Omaha and there retorted. What percentage has been saved is not now known. The probabilities are the loss is heavy. Insurance adjusters are due from Chicago to-day or to-morrow. Their labors will be brief, and it is hoped and confidently believed that settlement will promptly follow. Until, however, these preliminaries have been concluded, no meeting of stockholders is likely to be held, and consequently nothing official can therefore now be promulgated. Conversation, however, with a number of parties owning stock in the company, has convinced the reporter that all of them are in favor of rebuilding as speedily as possible, and are willing to meet any assessments which may be found necessary. Besides this, it is only half a secret that other parties of ample means to carry out their purposes have about made up their minds to put up works of their own. Thus we are certain to have one plant as large as that destroyed last Friday, and have fair prospects of another of equal capacity.

MEN DISCHARGED.—Deadwood *Pioneer*, March 2: One effect of the destruction of the reduction works was the immediate discharge of the entire force—21 men—at the Golden Reward, and also the cessation of work at the Ruby Bell, Maggie and one or two other Bald mountain corporations.

IDAHO.

A STRIKE IN THE SOLACE.—Wood River *Times*, March 9: News comes of a strike which was made in the Solace mine, at Vienna, about two weeks ago by the leasers. They struck a vein which carries from four to six inches of ore assaying between $400 and $500. The strike was made below the old tunnel level.

CŒUR D'ALENE MINES.—Wardner *News*, March 2: Spring is with us at last, our mountains have doffed their snow caps and old winter with its chains of ice and clogs of snow has gone where the woodbine twineth. How different our climate from that of the East. There, February and March are often the worst two months, and even in April plenty of winter weather exists. Cœur d'Alene offers greater attractions than any other portion of the Northwest, not only to the traveler but also to the speculative man, who seeks to combine business with pleasure. While enjoying the salubrity of our mountains the capitalist can find the very best opportunities for profitable investment. Miles of the richest mining country known to man are open for inspection, while our old and well-developed mines yielding up their thousands daily and weekly is a spectacle that never fails to interest, but always enlists the attention of the enterprising and ambitious observer. The coming season will be one of unusual activity and prosperity. The amount of development work in our various districts will exceed all previous records, while the quantity of rich ore brought to the surface will more than realize the expectations of those interested in the product. New machinery will be erected at various points, the number of our mills will be vastly augmented, and our immigration will be in keeping with the great advancement of the country. Let the workingman and capitalist both come. The field for each is proportionally good, and while the first named cannot fail in bettering his condition, the latter will find, if he has the money, we have the mines to command immediate attention, while they are fully worth all the capital that can possibly be invested in them.

MILLING NOTES.—The concentrating works of the Stemwinder Co. at Kellogg resumed work on Wednesday morning, and the bucket tramway is again in motion conveying ore from the mine above Wardner to the mill. The Poorman mill at Burke recommenced operations this week and will continue to supply its concentrates uninterruptedly. The machinery of the Hunter mill at Mullen is all in place, and will be started in about two weeks.

MONTANA.

GEORGETOWN GOLD MINES.—*Inter Mountain*, March 7: A proposition is understood on pretty good authority to be on foot for the sale of the Pyrenees mine and mill at a big figure. The mill has been running steadily for several years and the output of gold bars has been large. The latest development in the Southern Cross is in the east drift from the 250-foot station. The face of the east drift is seven feet from the shaft and is in fine ore. The Red Lion Co., which owns a property about ten miles north of Georgetown, yesterday hauled in the material and machinery for a five-stamp mill. The directors expect to put up their mill within 30 to 60 days. At Silver Lake the fine prospect of a mining boom has caused the springing up of quite a town. Some 20 houses, of logs, are in course of construction.

THE MINNIE PALMER MINING CO.—*New Northwest*, March 9: Mr. Sam Ritchie, manager of this company operating on the Minnie Palmer lode near Beartown, is very much elated with the showing he now has on the property. They have run 415 feet on the tunnel and have not yet struck the lode, which has dropped at an angle of 45 degrees. Sixty-five feet of this tunnel have been driven since Dec. 8th, when the new company began work. It is now in talcose slate and believed to be near the vein. But on Jan. 24th they began again on the shaft, sunk it 10 feet, cut out a station and run a level eastward 28 feet on the ledge. It shows ore 8 to 10 inches wide at the top of the level and two feet at the bottom of the level, all apparently free milling gold ore. The walls are five feet apart, a granulated limestone footwall and a granite hanging-wall. The quartz is in a body on the hanging-wall and the balance of the vein matter is talc and stringers of quartz. Mr. Ritchie brought up what he believed to be fair average samples, from which Mr. Strang, assayer, got the following results: No. 1, $82.50; No. 2, $100.50; No. 3, $240 25; No. 4, $241.00; average, $144.06. This Mr. Ritchie believes a fair average of the two-foot body.

BONDED TO ARIZONA PARTIES.—*Mining Review*, March 9: We learn that Wm. Dolman & Co., who are operating on Johnnie's Gulch, about 12 miles from Radersburg, have bonded their property to Arizona parties for $50,000, with a payment of $2000 down, the bond to expire in 30 days. This is the prospect which was mentioned some time since as being so promising. The ore is dry in character and of very high grade. The vein stone is composed of baryta, or heavy spar, which is considered by mining men to be the very best indication of permanency.

NEW MEXICO.

DEVELOPMENT WORK.—Silver City *Enterprise*, March 9: Charles Brakebill is taking out some fine horn silver ore from his Bear mountain mines. Fielder and Ward are pushing work on the Centralia. They made a shipment of ore last week. The Aztec, 300-foot level, north drift is now carrying 20 inches of ore and widening northward. It is settled, for the present at least, that the Aztec and Pacific mills will be located just above this city. Lindauer and Woods are working eight men on the Central mine, Central district. They have 60 or 70 tons of ore on the dump. A strike was made in the south drift of the Wagner lead at Pinos Altos this week, that surpasses all former discoveries. The ore streak is three feet wide and runs 1½ ounces in gold. Johnson and Fowler, of this city, have a lease on the San Jose copper mine, and are putting it in shape for extensive working. E. G. Payne and John Spiller have leased the Rain-in-the-face mine and mill, in East camp, and will resume active operations there at once. The Aztec mill started up again last Tuesday morning, and will continue to run steadily unless the roads again become unpassable. Downey, Dennis and Gleason, who have the American mine, Hachita, under lease, are taking out large quantities of ore for shipment to El Paso. The ore runs high in iron and averages about $40 in silver. Superintendent Harrison of the Pacific will shortly commence the sinking of a development shaft on the Cleptomania vein of the Pacific. B. B. Lewis and Col. H. L. Pickett have leased and bonded the Smith and Ailman mine and mill at Pinos Altos. Work was commenced on the mine under the new management to-day. Denver parties have secured a bond and a lease on the Thunderbolt zinc mine, Hanover district, owned by "Scotty" Mungall and Mrs. John Black. They will commence work on the property in a few days. The general impression seems to prevail that the Mogollon country is on the eve of a grand mining boom. The last two coaches from that section have each brought down a handsome silver brick, the output of the Cooney five-stamp mill. Mr. Cooney assures the *Enterprise* that he has an abundance of ore for a 20-stamp mill, and the probabilities are that he will have a plant of that capacity running ere long. All of the mines now being worked in that section seem to be doing well. The reckless wild-cat days have passed in that camp, and mining is now being carried on in a legitimate manner.

OREGON.

BAKER COUNTY MINES.—Bedrock *Democrat*, March 7: The mildness of the past winter and the slight snowfall has been most favorable for the working of the numerous quartz mines of Baker county, and development work has progressed without interruption all winter. In the districts of Sumpter, Cracker creek, Cable Cove and Granite is this noticeable where all of the more prominent mines have been worked continually and the most favorable results obtained. These districts never presented a more encouraging outlook than at the present time and will stand the inspection of the most competent experts that ever made an assay or wrote a report. The Cracker creek mines—the Eureka & Excelsior, Columbia, North Pole, Gray Eagle and dozens of other locations in the immediate vicinity, never looked better and have developed to the extent that there is no longer any speculation as to their merit. They are mines that any country could well feel proud of. The Eureka & Excelsior, owned by a St. Louis syndicate, have been developed to a high state of perfection and the wealthy company owning them have made arrangements for the erection of a large mill, some of the machinery for which has already been hauled from this city to the mines. The same may be said of the Columbia company. The mine has been under rigid development all winter under the superintendency of H. Stevenson, who has had in his employ from 25 to 30 miners. A mill will be erected on this property at an early day. A mill will also be erected on the North Pole mine, owned by an English company, early in the season. The Gray Eagle is now listed for sale to a wealthy Eastern syndicate and the sale of the property is assured. The La Bellevue, in the Granite district, is said by every one who has inspected it to be the best mine on the Pacific coast, and the result of practical demonstration certainly proves it. Carload after carload of concentrates have been hauled to this city this winter and shipped to Salt Lake for reduction, and the returns have been magnificent.

WASHINGTON TERRITORY.

CONCONULLY.—Ellensburg *Capital*, March 8: Mr. McGrath, who has been absent in the mines of Conconully for the past month, has returned to Ellensburg, bringing good reports from all the districts. He sold the third interest of McGrath & Palmer in the War Eagle and Black Bear, in Wanicut district, for $4000, or at the rate of $12,000 for the whole property, which is a good price for it in its undeveloped condition. He reports considerable activity in the way of development and great confidence in the richness and permanency of the mines. Capital is being interested and the prospects of ore output of considerable magnitude are quite flattering.

MECHANICAL PROGRESS.

Effect of Rolling and Wire-Drawing Upon Mild Steel.

An interesting paper was recently contributed to the British Institution of Civil Engineers by Mr. Horace Allen, which is summarized by the *Ironmonger*. That gentleman made a series of tests in order to prove that the manipulation of steel, during its formation into wire, had greatly increased its tensile strength. He selected a mild-steel billet, two inches square in section, and having the following chemical composition: Carbon 0.115; silicon, 0.009; sulphur, 0.068; phosphorus, 0.072; manganese, 0.410, and iron, 99,326. A portion of this billet was turned down for testing, and sustained a breaking load of 28.08 tons per square inch, with an elongation of 28.1 per cent. Another portion of the billet was rolled into wire rod. In this case the rods were found to have increased in elastic limit by from 17 tons in the billet to 25 tons in a No. 5 wire rod, or an increase of 47 per cent. The breaking-stress was raised in all cases, a No. 1 rod increasing from 28 to 32 tons. The reduction of area at the point of fracture was increased in all the specimens, being from 54 per cent in the billet to 67 per cent in the No. 5 rod. The specific gravity was increased by rolling from 7826 in the original billet to 7865 in the rolled wire rod, and 7852 in the annealed wire rod.

The author of the paper says it is evident that the density of the steel is considerably and permanently affected by the effect of rolling the iron. Although the billets were strongly heated before the commencement of rolling, the temperature fell rapidly during the operation, on account of the sectional area becoming very much reduced; and the temperature of the finished rod, on leaving the rolls at a red heat, continued to fall rapidly, consequent on the relatively large surface of the rod, the molecules of which had not time to rearrange themselves in the same manner as they probably had done in the billet, in which case the section of the rolled steel was comparatively large, and the rate of cooling much slower. The alteration in the physical properties of the wire rod, compared with the original billets, as shown by the increased elasticity and tenacity and diminished elongation of the rod, is doubtless due in some measure to the effect of rapid cooling in the process of manufacture. This is proved by the fact that after annealing the wire rod, by placing it between pieces of white-hot steel and allowing them to cool slowly together, the results of tensile tests showed that the steel was brought a little nearer to the condition of the original billet. Rolling the steel down to such small sizes at a high temperature induces absolute molecular contact, closing up any microscopic cavities left in the steel when in the form of a billet. This probably accounts, to some extent, for the increase of the elastic limit and breaking-stress, because the continuity of the molecules is less broken than in steel which has had less work upon it. Mr. Allen deems remarkable the increased contraction of area in the wire rod. Generally, the effect of putting mechanical work upon steel is the production of increased tenacity, accompanied by a diminished contraction of area, yet in wire rod the tenacity and the contraction of area are greater.

IRON AND STEEL ANALYSES.—W. Shimer Porter has recently described a new method for the estimation of phosphorus in iron and steel, which gives very accurate results. The procedure which he recommends is as follows: One gramme of the iron is dissolved in 20 cubic cm. of nitric acid, 20 cubic cm. of potassium permanganate solution of known strength is then added, and the peroxide which is produced is dissolved by means of hydrochloric acid. Sulphuric acid is next added to the mixture, and the solution is evaporated until sulphuric acid fumes are given off. The residue is then dissolved in dilute nitric acid and filtered. In the filtrate the phosphoric acid is precipitated by means of ammonium molybdate solution. Two new methods for the estimation of the sulphur in iron and steel have also been published by Messrs. Arnold & Hardy. They are both based on the fact that when iron is in a finely divided state, on heating with dilute sulphuric acid all the sulphur present is evolved as sulphureted hydrogen. The gas produced is absorbed and its amount determined either by a calorimetric or volumetric method. The former plan is the shorter of the two, and both give very satisfactory results.

BRAZING WITH BRASS OR COPPER.—A correspondent of the *Blacksmith* describes his way of doing such work as follows: "I file the parts to be joined clean, wire them in place or rivet them; then take a few lumps of borax and burn them on a piece of sheet iron, then pulverize them, dissolve some on the article to be brazed in it, then lay on the piece of brass or copper, tie it fast, sprinkle some of the borax over it and put it in a clear fire, blowing very slow at first till the iron gets red; then I will see a blue flame which is the melting point of brass and copper. I allow it to lie in the fire a minute without blowing, then take it out and lay it down gently on the hearth to cool. Very delicate articles should be dipped in a batter of clay to keep them from burning. When the clay begins to glaze it is time to take them out of the fire. Brass of copper should be brazed with silver. Copper can be brazed with brass, but the melting points of copper and brass are only a few degrees apart, and no such work is safe unless you have to deal with a large piece of copper. Brass and copper for brazing should be melted. When silver is used it should be old coin or Mexican coin—such silver being purer. The blowpipe is the best to braze with, but it requires some practice to use it successfully."

Pyrometers—What They Are.

The methods employed for the determination of high temperatures—the temperature of furnace fires, flue gases, molten metals, etc.—may be divided into four classes: (1) Those which depend for their indications upon a change of dimensions of a body employed in the test; (2) those based on the amount of heat imparted to a body of water or air by the heated body; (3) those dependent upon the melting points of metals and metallic alloys; and (4) those dependent upon the measurement of the electrical resistance of metals.

The first method was employed by Wedgewood, who constructed, in 1782, the first instrument by which high temperatures could be measured with any approach to accuracy. His instrument is based on the property possessed by clay to contract when exposed to high heat, an effect which is believed to be due partly to the loss of its water and partly to the process of vitrification which sets in subsequently. It has been found, however, that the assumption by Wedgewood that the contraction of clay is proportional to the degree of heat to which it is subjected, is incorrect; and that a long-continued heat of moderate intensity will cause the same amount of contraction as a more intense heat for a shorter time; and, further, that different clays differ considerably in the degree of contraction which they suffer when subjected to the same temperature. For these reasons, the method of Wedgewood has been abandoned in scientific measurements, as unreliable, although it gives results in many cases approximating sufficiently to the truth for all practical purposes.

In the pyrometer of Daniell the temperature is measured by the expansion of a metal bar inclosed in a black-lead earthenware case. The metal of the bar is either platinum or soft iron. The expansion of the bar causes the motion of an index of porcelain on a suitably graduated scale. The second method, which is that most generally in use in metallurgical operations, consists in placing a mass of platinum of known weight in the medium whose temperature is to be ascertained, and, when it has acquired the same temperature, plunging it into a body of water of known weight and temperature. From the indicated rise of temperature of the water, the known relation between the weights of the platinum and the water, and their relative specific heats, the data are given for the estimation of the temperature to which the platinum was originally heated.

A method similar in principle to this is in common use to determine the heat of furnace and flue gases. It is based on the plan of mingling with the heated furnace or flue gases a definite volume of air of known temperature, the assumption being that if an equal volume of air is mingled with the hot gases, their temperature will be reduced one-half; if twice the volume, two-thirds; if three times, three-fourths; if nine times the volume, nine-tenths, etc. By thus mingling a large volume of cold air with the hot gases, the temperature of the mixture will be reduced sufficiently to permit it to be measured by means of thermometers, or by the expansion of a metal bar.

The third method, based on the melting points of certain metals and alloys, is practiced by simply suspending in the heated medium a piece of metal the melting point of which is known, or, if necessary, several pieces of different (but known) melting points. According to the observation of the pieces which are melted, and those which continue to remain solid, the temperature of the medium may be ascertained within a very narrow limit of error.

The fourth method is a much more refined and scientific one, devised by Siemens, and is based on the principle that the electrical resistance of metals stands in a certain relation to the temperature, an increase of the latter causing a corresponding increase of resistance. The resistance of a given piece of metal of known material and dimensions being ascertained by measurement with the aid of suitable apparatus, its resistance for any given temperature can be calculated, and vice versa. This treatment will be found described in the special treatises on electricity.—*Manufacturer and Builder.*

IRON PIPES.—We read that less than a century ago iron pipes did not practically exist in Great Britain, and yet it is undeniable that the use of pipes dates back to a very early period. In a description of the palace of Abdurrahman III, extant about 750, and situated at Zahra, in Spain, we find that metal pipes were used to convey both hot and cold water to the marble baths. A year after the battle of Waterloo iron-flange pipes were cast in 2½-feet lengths, and packed at the joints with old hats. In 1811 and 1817 patents were taken out for welding barrels of fire-arms, and in 1824 Mr. James Russell took out a patent for constructing iron tubing, but about a year after Mr. Whitehouse took out a patent for an improved system, which was the beginning of our great tube industry.

SCIENTIFIC PROGRESS.

The Order of Nature.

Dr. Jenkins is unfortunate in confronting the kind of "exceptions" which I aver science cannot recognize with the fact that water, in opposition to all other material substances, expands under a certain degree of cold. But is there any known exception to this law of water? Has water ever been known to reverse this process in freezing? If so, the exception would indeed stagger science—it would be a miracle. A child born of a woman, but without an earthly father, and of a superhuman species, is the kind of exception which I averred science cannot recognize. But does this bear any analogy to the exceptional behavior of water while freezing, when compared with other substances? It used to be believed that in every animal that possessed a circulation, the blood always took one definite and invariable direction; but in 1824, Huxley says, it was discovered that a class of animals called *Ascidians* furnished an exception; the heart of these animals, after beating a certain number of times, stops, and then begins to beat in the opposite way, so as to reverse the course of the blood, which returns by-and-by to its original direction. Such an exception does not disturb the man of science; it only teaches him greater caution in making his deductions. But if one Ascidian, and but one, could be found whose heart beat like that of other animals, that would be a puzzle to him; or, if one comet, and only one, should appear, carrying its tail toward the sun instead of from it, cometary astronomy would be reduced to chaos. A floating feather is no exception to the law of gravitation, but a floating stone and a falling feather would be an exception. Science as well as experience finds exceptions to general rules everywhere, but these exceptions are constant and as strictly the result of natural law as anything else. Faith in the continuity of nature, upon which the scientist builds, no less than every man in the conduct of his life, does not mean sameness or identity of all physical processes, but it means identity of these processes under like conditions. Given the same conditions, and the same results always follow.—*John Burroughs in Popular Science Monthly.*

CHANGE OF MOTION INTO HEAT.—The opinion is now commonly accepted by scientific men that all bodies, substances, gases and liquids, are composed of multitudes of particles or molecules of almost inconceivable smallness, and these are supposed to be in motion among themselves—this motion, moreover, being heat; that is to say, heat is neither more nor less than a kind of motion, and this internal vibration can be transmitted into a perceptible mechanical movement; or, on the other hand, mechanical movement can be converted into the invisible motion called heat. How the change takes place no one knows, but the change is none the less a fact. As illustrating this point, a writer in the *Mechanical Engineer* cites the fact that the difference between a solid and a gas is simply that the motion of the particles or the molecules of the gas is much greater in extent than is the motion of the particles of the solid, some gases also having a greater range of motion than other gases; and if by any means the motion be taken out of gas, say by compressing it into a vessel, the sides and ends of which reduce the range of movement, then, as nothing is lost in nature, the invisible and insensible motion of the gas, which it has lost, reappears as heat in a visible form, and it is found that the sides of the vessel become hot. Further, the oxygen, which has combined with coal, has a very considerable range of internal motion, but when the oxygen has combined with the coal, another gas, known as carbonic acid gas, is produced; and, the particles of this gas having a much smaller range of motion than the particles of the oxygen have, the difference appears in the form of heat.—*Boston Journal of Commerce.*

BRASS TUBES FOR CLOCK BELLS.—It has been found that brass tubes, when properly annealed, and suspended in a vertical position from a point near the top, and struck at a point above the point of suspension, have resonant qualities far superior to bells, especially when comparative weight and cost are considered. This fact has been made the subject of a German patent, and tubes are being used there for chimes in church towers. Some idea of the comparative efficiency of tubes for the purpose is obtained from the fact, as stated, that a tube three inches diameter outside and one-half inch thick, 12 feet long, can be easily heard a distance of one mile, and under favorable circumstances two or three miles. Walter H. Durfee of Providence, R. I., is making use of these tubes for chimes, which are rung by the clock movement at regular intervals.

EXPERIMENTS WITH LIGHT.—Dr. O. J. Lodge, a holder of the theory that light is an electrical vibration of the ether, has been endeavoring to produce these waves by direct electric action without the intervention of heat. The means adopted was the oscillating discharge of a Leyden jar, with a rate of vibration as high as 1,000,000 per second. The waves thus obtained were about three yards long, but, according to Dr. Lodge, were light in every particular except wave length. To reach the wave length of light, however, they would require to be shortened from three yards to the hundred-thousandth of an inch. The electrical waves of Dr. Lodge travel through space at the same speed as light, and are refracted and absorbed by material substances according to the same laws. Hence Dr. Lodge concludes that if we can only generate electric waves sufficiently small we may entirely revolutionize our present modes of obtaining artificial light. In connection with this subject, we may refer to the important discovery which has been made by Dr. Hertz of Vienna, to the effect that blue light is capable of starting the electric spark when it otherwise would not pass between the sparking points. That is to say, for example, that if the sparking points of an induction coil be drawn just too far apart for the spark to leap across the intervening air, a ray of violent light falling on the gap will start the spark. Dr. Oliver Lodge infers from this discovery that the mere blaze of one lightning flash may precipitate other flashes.

WATER HEAVIER AT NIGHT THAN IN THE DAY.—Some one who has evidently been reading wishes to know if it is true that water is a trifle heavier at night than in the daytime, and if so, how much does it amount to. It is well understood by mechanics in general that the sun's attraction, if it amounts to anything at all, must attract upward at midday as much as it attracts downward at midnight, and however slight this attraction may be, it must make a difference in favor of a greater driving force to work with in the night-time. The force of the sun's attraction amounts to one pound in a mass of water of 146 cubic feet. If half of this amount of water could be weighed at midday and again at midnight, it would be found to have gained a pound in weight, as a half pound has been added and then subtracted by the operation due to the sun's attraction, but it will not do to test this action on a set of Fairbanks' scales, as the sun will attract the weight on the levers as well as the weight on the scales. Something like the spring balance must be used. —*Boston Journal of Commerce.*

WHY CAR-RAILS IN ACTIVE SERVICE DO NOT RUST.—The fact that car-rails in active service seldom suffer deterioration from rust, while others less used do, is susceptible of a very simple explanation. The iron hydrate, the ordinary iron rust, is forced by the pressure of passing wheels into combination with the iron of the rails, forming a magnetic oxide which protects the rail from further action. The rust which forms on all rails during a rain or damp weather has hardly time to dry before this combination takes place on the rails in active use. In an experiment quoted in proof of this explanation, the scales on that surface of a rail which received the greatest pressure were removed by the aid of a wire brush and submitted to analysis. They were found to be composed of magnetic oxide mixed with a variable quantity of ferric oxide, and apparently a small proportion of free iron.

CURRENT COUNTERS.—A very ingenious current counter has been devised by Prof. Geyer and Mr. Bristol, two American electricians, which is equally adapted to the measurement of direct and alternating currents. Two pieces of German silver—one a flat band and the other a fine wire—have their ends soldered together. On passing a current through the composite strip the fine wire loses heat more rapidly than the flat band, and consequently attains a higher temperature, deforming the strip in much the same way as in Breguet's metallic thermometer, and this deformation is a measure of the intensity of the current. By suitable arrangements a record is formed on a paper band.

A POSSIBLY NEW TEXTILE.—A French paper reports that from a plant called kanaff, which grows in the summer on the shores of the Caspian, M. G. Blakenbourg, a chemist, has obtained an admirable textile matter, which is soft, elastic, tough and silky, and which can be bleached chemically without losing these properties. The resistance of this new material is said to be far greater than that of hemp, while its specific weight is much less.

NICKEL FOR LIGHTNING RODS.—It is reported that at Dresden the experiment has been tried of placing a nickel lightning-rod on a building. The advantages claimed for this metal are that, being non-corrodible, it will last longer than iron, and will also keep bright at the points, which latter is very essential to the efficiency of rods as conductors of electricity.

HAS BECOME EXTINCT.—One of Scotland's rare marshy plants, the Scheuchzerta palustris, a genus of the order of arrow grasses, has, according to Prof. Hillhouse, become extinct. It was to be found only on the moor of Methven in Perthshire; but some 300 or 400 black-headed gulls have settled down on this moor and annihilated every trace of vegetation.

THE ELECTRIC LIGHT IN LONDON.—The great central station at London which is to supply electric light on an extensive scale for the city is being built with facilities for furnishing 250,000 incandescent lights in the near future, and a final capacity of 1,000,000 lamps.

THE FIRST PHOTOGRAPHER.—The man who made the first photograph ever produced in the United States, Franz George Schreiber, is still living in Philadelphia, hale and hearty, at the age of 86.

GOOD HEALTH.

The Passion and Danger of Anger.

Anger is a passion most generally excited on the moment, which subsides more or less rapidly, according to the nature of its cause. It always exerts a powerful and deleterious influence upon the system, which becomes augmented in proportion as the passion approaches toward insanity, as, when it becomes furious and ungovernable.

A person in a fit of anger may be at once recognized by the redness of the face, the furious sparkling of the eyes, and the violent agitation of the whole system. Some are unable to speak, while others are extremely voluble and vociferous; not unfrequently, persons foam at the mouth in a fit of anger. Some persons when angry, gesticulate violently, stamp their feet and display an uncommon degree of physical strength; others involuntarily shed tears.

Violent anger is very deleterious to health, and the more often it is suffered to be aroused, the more frequently will it develop itself upon even trivial causes. From its action upon all the functions of the system, it is liable to cause epilepsy, the rupture of a blood-vessel, convulsions, fainting, apoplexy, and even sudden death. Moderate anger is apt to be longer continued, and accompanied with hatred, malice, revenge, regrets, etc., rendering the person fretful and petulant, and gradually inducing some permanent disease. They who lead a life of voluptuousness and dissipation are the more ready subjects of this passion. Suckling infants have often been thrown into convulsions after having partaken of the breast-milk of a previous angered nurse.

To overcome the propensity to angry feelings requires much resolution and perseverance. As with fear, it is necessary to have a constant watch upon our minds, maintaining a degree of presence of mind upon the most sudden emergencies, and promptly repressing every angry feeling as it arises. The most powerful means of suppressing this passion is at once to concentrate the whole of the mental powers and resolve to overcome it; let the higher powers of the mind control the person. It is the power of thinking, reasoning and judging that renders man superior to the brute. When angry, contentious words only tend to fan the flame; it is better, therefore, to be silent, to take a draught of cold water, to withdraw one's self from the exciting cause, or adopt any other simple means, until the anger has passed away and reason resumed its sway. Never attempt to settle business when the mind is in an irritable or fretful condition. Persons of an inflammable disposition should be temperate in food and drink, especially avoiding the use of stimulating food and intoxicating drinks. The true gentleman, the man of proper education, can always hold command over this passion.

Children should be carefully guarded from those causes which will arouse and cultivate their angry passions. Improper punishment, dispppointments, tyrannical conduct, partial justice, etc., should be carefully avoided. Children have their rights, which should be held sacred by every parent and teacher. Instead of being treated as mere machines, slaves, or brutes, they should be governed by such methods as will repress evil and cultivate virtuous propensities, remembering that they are but men and women in miniature, possessing every mental attribute common to the adult, though more keenly susceptible and alive to external impressions. "Train up a child in the way he should go, and when he is old he will not depart from it," is a truth too little understood, or too little acted upon in the present age, for instead of training and properly educating them, they are more frequently driven up as one would drive cattle to market.—*Yolo Democrat.*

THE CARE OF THE NAILS.—Very few people know how to properly care for the nails. In cleaning them a sharp knife ought never to be employed, but between the ends of the nails and fingers the space should be filled with soap, and then removed by brushing them with the so-called nail-brush. Many improperly cut away that part of the flesh which grows over the nail from the bottom; but it should be simply pressed backward, and sufficiently to show the white part, considered by some to be a mark of beauty. If the flesh is adherent to the nail, the operation may be facilitated by passing the sharp point of a knife underneath the fold of flesh and separating it from its attachments. With this done, it can be pushed back more readily. Scissors should never be used to cut the nails; that should only be done with a sharp penknife.—*Boston Journal of Health.*

DANGER IN THE CORN-COB PIPE.—"Your head aches, your eyes bother you, and your throat is always parched," said a well-known physician, diagnosing the case of a patient. "Now, I can tell just what brings on these difficulties. You smoke a corn-cob pipe. Isn't that a fact?" The sufferer replied in the affirmative, but was curious to know how the doctor learned what kind of a pipe he used. "I see so much of this that I couldn't help knowing what ailed you," explained the medical man. "Men apparently enjoying perfect health come to me every day. They are great big robust fellows, and they all suffer from the same cause. At first I was nonplussed, and led myself to believe that it was a new disease, but I finally discovered that the whole trouble was caused by corn-cob pipes. It needs no credulity on your part. Notice yourself when you are smoking a corn-cob, a sickly, overpowering odor, which fills up your throat and lungs and causes a smarting sensation of the tongue. That is the smoke of the burning cob, and it contains enough creosote to cure a ham."—*N. Y. Sun.*

NATURE'S METHODS.—Dr. Wythe, Professor of Microscopy in Medicine, lectured on "The Bright Side of Disease" at Cooper Medical College some time since. He said disease was not a wicked demon, as the Chinese believe; not an effort of nature to throw off morbid matter; not an affair of the imagination to be cured by an effort of will—all these were bugaboos. Nature's methods should be observed. "Take, for instance, a fainting spell," continued the doctor. "The prostrate position into which a fainting person falls is the best possible posture. Consequently, a person who has fainted should never be lifted to an upright position. In a fever one wants liquids because the stomach is weak and cannot digest solid food. A physician's duty is not to prescribe an antidote, but to remove obstacles in the way of nature, then the *vis medicatrix naturæ* will do the rest. When a limb is broken and the surgeon has fitted the broken parts together, Nature pours a kind of fluid all around them which hardens into a perfect cylinder, fitting the bone exactly. Besides this, a plug appears in the hollow center of the bone, uniting the parts until perfect union has taken place. Then cylinder and plug are gradually dissolved."

ICE AS A REMEDY.—Prof. Stewart, after telling us that the seat of nausea is not in the stomach, but in the brain, informs us that relief from this distressing sensation may be obtained by cooling the base of the brain. He has tested this often and thoroughly in the case of sick headache, bilious colic, cholera morbus and other ills in which nausea is a distressing symptom, without a single failure; and once relieved the nausea resulting from cancer of the stomach by the application of ice to the back of the neck and occipital bone. The ice is to be broken and the bits placed between the folds of a towel. Relief may be obtained by holding the head over a sink, or tub, and pouring a small stream of water on the back of the neck. This is worth remembering as a relief for sick headache, to which so many women are subject.

POISONOUS MACKEREL.—There has been a correspondence in the *British Medical Journal* on the subject of poisoning from the eating of mackerel. Details are given of several cases, and in commenting upon them, Dr. A. W. Flood, surgeon R. N., retired, writes from Bandoran: "I believe the cases that I have seen were caused, not by eating the mackerel when out of season, but rather to the fish being too long kept, and, in addition, being exposed on a cart to the heat of the sun for sale. I believe mackerel to be a most dangerous fish for food, unless great care be taken to get them fresh, as ptomaines are developed very rapidly in them. I may say the residents here do not consider them safe when they are more than 24 hours out of the water."

USEFUL INFORMATION.

WHY PHOTOGRAPHS ON CARDBOARD GROW DIM WITH AGE.—Common photographs, in which the dark parts consist of finely divided silver on a film of albumen, rarely remain unchanged in appearance for 20 years. The white parts sooner or later take on a sickly yellow tinge, and when this change has begun the picture is doomed unless immediate steps are taken to preserve it. Treatment by skillful hands with a weak solution of mercuric chloride (corrosive sublimate) may arrest decay, but will not restore the clearness and freshness of the print. A better plan is to have the picture copied by some platinum-printing or carbon-printing photographer who does a large enough business to employ a skillful retoucher. The process of getting a good, permanent photograph from a bad, fading one is complicated and requires skill. Photographs in which the dark parts are formed of platinum-black are the most durable sort known. The best photographers will furnish permanent pictures if their sitters demand them, but such pictures are in plain black and white—without the chocolate tinge of the common style—unless the carbon process with a pigment of the requisite color is employed. The greatest enemies to the permanence of common silver-prints are traces of chemicals not fully washed out of the print, dampness and the action of sulphur or its compounds. The last of these agencies is the most difficult to guard against. The albumen with which the photograph paper is coated contains sulphur, and a familiar instance of its action is the blackening of silver eggspoons. The air also, especially in cities, contains sulphurous gases derived from sewers and from the burning of coal and gas.—*Popular Science Monthly.*

HOW TO MAKE AN ÆOLIAN HARP.—The simplest style of this melodious instrument is that which fits into an ordinary window-frame. Out of thin, well-planed boards of common wood make a box as long as the window for which it is intended is wide, four inches deep and five inches wide. Glue the pieces together, making the joints as true and clean as possible. The boards, by the way, should not be thicker than one-eighth of an inch, and the more carefully you make the box the better the harp will be when it is done. Three inches from each end of the box, glue on a bridge for the strings to pass over. The bridges should be made of some kind of hard wood. The strings are of catgut and are tightened by means of pegs fitted into holes bored for the purpose at each end of the box. Six or eight strings may be used, and they should be tuned in unison. Three inches above them place a thin board supported on four pegs, one at each corner of the box. Then put the box in the window and bring down the sash on the upper board. The air passes in and out between it and the sounding-box, and the strings, being set in vibration by it, give off that soft, melodious murmur for which the æolian harp is noted.

A PEAR TREE OVER THREE CENTURIES OLD. The *Garden* (London) gives the following description of a remarkable French pear tree, which, although over three centuries old, is still bearing fine fruit in abundance: There exists in the garden of M. Mengnot, at Pollet, France, outside the town of Dieppe, *Seine-Inferieure*, an espalier pear tree, the oldest and largest that probably can be found in Europe. This is a tree of the pear Oueillette or Epargne, grafted on the free stock; it is planted against a wall eight meters high, and in a clayey soil. The stem is one meter in thickness; each lateral branch is 70 centimeters in diameter; it is 30 meters in width, and is in a southern exposure. Its growth is vigorous, and the tree bears each year from 3000 to 4000 pears. Its date of planting, written on a stone placed in the wall, was 1580, in the reign of Henry III. The property where it was found planted was formerly a hospital. This venerable tree is taken care of by the owners, so that even now a long life is assured it.

THE MARINER'S COMPASS.—The statement that the compass was invented by Flavio Gioia, or Fra Diavolo, or some other Dutchman, has long since been declared erroneous. As early as 1268 Pierre de Maricourt not only described the compass, but calculated its variations, and the calculation shows that the needle wobbled with as much certainty then as it does now. Paul must have been familiar with the compass, for we are told that he "fetched a compass." We are not told, however, where he fetched it from, or why he hadn't it on board when he started.

THE REVOLUTION IN SLEEPING CARS.—In view of the movement in some States to compel a reduction of sleeping-car charges, it is reported that the Pullman Company contemplates furnishing a less luxurious car, to be used on roads in States where such laws may be enacted. A person interested in the business is quoted as saying: "The States that insist on cheap fares are to have cheap cars."

ODDS AND ENDS OF SOAP.—Every piece that becomes too small to use, lay aside, and when a sufficient number have accumulated, boil them in a little hot water till all are melted, then pour into a mold, and when cold you will have a nice cake of soap. You can use a glass dish for a mold by heating it thoroughly before pouring the melted soap into it.

INK STAINS may be removed from silk or woolen goods by saturating the spot with spirits of turpentine and letting it remain several hours, then rubbing it between the hands. To remove ink stains from cotton and linen goods, apply alternately a strong aqueous solution of oxalic acid and chloride of lime; then rinse well in clear water.

RAILROAD CROSSINGS.—According to the report of a Massachusetts legislative committee, all the grade crossings of railroads in that State must be abolished. There are 2902 intersections of highways and railroads, and to carry out the purposes of the law would necessitate the expenditure of $48,000,000.

NATURALLY REFINED COAL OIL. — What proves to be a veritable gold mine, says a Pittsburg paper, is an oil well on the Summerville farm, near Brady's Bend, which is producing pure refined oil. The output is about one barrel a day. The oil is clear, odorless, and a fine illuminant.

KEEPING PIANOS IN TUNE.—A French engineer has recently invented an improved key, which, it is said, simplifies and renders lasting the tuning of stringed instruments. The violoncellists of the Grand opera at Paris have had them adapted to their instruments.

THE advantage of technical schools has been illustrated in Crefeld, Germany, where over $1,000,000 has been spent on its lower schools, and $250,000 on a special weaving school. It has doubled its population and quadrupled its trade.

WROUGHT IRON can be made to contract to some little extent by heating it to a low red heat and quenching it in water. The first heating is the only one really effective, as subsequent heatings make little or no difference.

COPPER may be hardened by melting with it and thoroughly stirring into it 1 to 6 per cent of manganese oxide. The other ingredients for bronze may then be added.

ENGINEERING NOTES.

MARVELOUS RAILWAY GROWTH.—The *Railway Age* has published a most interesting table, showing the increase and decrease of earnings of the various leading railway companies of the United States for the year 1888. The companies which show a decrease are, with one exception, operating Eastern roads. Those which have made the heaviest gains are in the far West—notably in California. Thus, the New York Central shows decreased earnings from those of 1887 of $1,012,440; the Lake Shore, $677,027; the Chicago, Milwaukee & St. Paul, $503,124; and the Denver & Rio Grande, $319,153. On the other hand, the Southern Pacific shows total earnings of $43,000,000 in round figures, an increase over 1887 of $7,250,000. The Northern Pacific shows an increase of $4,186,882, and the Canadian Pacific, $1,589,681. Even the Atlantic & Pacific shows an increase of $338,346. These figures illustrate in a forceful way the tremendous growth and development going on in the Pacific States and Territories. The increased earnings of the Southern Pacific alone are more than one-third of the total income of the Lake Shore, and those of all the roads tapping the Pacific Coast combined are more than half of the total earnings of the Milwaukee & St. Paul, one of the greatest railway systems in the country. At the present rate of increase, what in ten years will be the total annual income of the railway system owned by Stanford, Huntington & Co.? The question is one worthy of thought by all who may feel apprehensive of the growth of monetary power in the hands of a few.

A CRADLE FOR AN ISTHMIAN SHIP RAILROAD. George M. Copeland, president of the Brockton city common council, according to a correspondent, has been working for 40 years on a plan for a ship railroad across the Isthmus of Panama. His plan includes a vehicle constructed in a cradle fashion, which is 400 feet long and 100 feet wide, resting on some 1600 wheels, the size of an ordinary car-wheel. These rest on an ordinary track, similar in construction to a railroad. The engines constructed for the purpose of hauling the vessels on this road across the isthmus are to be of 4000-horse power. Each engine has 200 large driving-wheels, and they are on either side of the cradle. These will give the engines as much power as that furnished on the largest ocean steamers. The cradle is eight feet deep, and is made of timber, bolted together, and provided with heavy rubber cushions at each joint, which will carry the largest vessel without jarring it in the least. On the inclined railway the cradle is run down into proper position. Then the vessel is floated over it. The roadway is composed of 16 parallel rails, 15 feet from outside to outside, in a bed not less than 125 feet wide at the top. Over this the cradle will readily travel at a speed of 8 to 10 miles an hour. Arrived at its destination, the vessel would be unloaded from the cradle by a reversal of the operation of loading.

THE MISSISSIPPI TO BE BRIDGED AT NEW ORLEANS.—The charter of a company organized for the purpose of building a bridge across the Mississippi a short distance above the city has been published. It is understood that the company proposes to build a suspension bridge which will span the river at or near Southport, in the Parish of Jefferson. For some weeks engineers have been at work running lines through the plantations and lands on both sides of the river. The general impression is that Collis P. Huntington, the millionaire president of the Southern Pacific railway system, is the moving spirit of the bridge company, and that he will build the bridge in order to more closely connect his Chesapeake & Ohio and Southern Pacific systems, and to have an unbroken railway line from the Atlantic to the Pacific Ocean.

REMARKABLE ENGINEERING FEAT IN CHINA. One of the most remarkable engineering feats appears to have been achieved in China, in the face of extraordinary physical difficulties, namely, the successful stretching of a steel-wire cable of seven strands across the river Lunann, this feat having been accomplished by the Danish engineer Delinde, assisted only by unskilled native labor. The cable extends between two points, at a distance of nearly 4700 feet apart, the hight of the first support being about 450 feet above the present level of the river, and the second about 740 feet. The cable in question is said to be the longest in the world, with a single exception, namely, the cable across the Kistna, measuring some 5070 feet. There are also two cables across the Ganges, of 2900 and 2830 feet respectively.

THE DANISH SOUND TUNNEL has found a successor in the shape of a projected bridge across the sound at its narrowest place, between Elsinore, in Denmark, and Helsinborg, in Sweden. The distance is there 18,000 feet, and the greatest water depth is about 70 feet.

LIEUTENANT FRED SCHWATKA, the Arctic explorer, started on the 5th to make an exploration of the country along the line of the Sonora, Sinaloa & Chihuahua railway from Deming south in the States of Chihuahua, Sonora and Sinaloa.

THE slightest vein of iron or steel can readily be detected by the application of aquafortis to the surface.

Passing Events.

The glorious rains which have fallen during the past week have been worth an immense amount to California. The agricultural and mining interests were both suffering, but this storm has set the streams running, filled the reservoirs and soaked the ground. All fears of a "dry season" are set at rest.

The mining excitement in Lower California still continues. It has attracted thousands of people, though late reports are by no means encouraging. In our mining summary and other columns considerable information is given concerning the new camp of Santa Clara.

The decision of Chicago capitalists to build large smelting works at Portland, Oregon, is of importance. If the works are established as proposed they will be of great benefit to the Cœur d'Alene region of Idaho as well as other sections in the Northwest.

It has been decided to rebuild the reduction works at Deadwood, Dakota, which were destroyed by fire last week. The works cost about $90,000, but were more or less experimental in their nature. It is unfortunate for the section that so disastrous a loss should have occurred just at this time.

The transmission of motive-power by electricity from the Sutro tunnel level of the Cholar incline to operate the Nevada mill in conjunction with the surface Pelton wheel, has proven a success, and will be a great thing for the Comstock milling interests. We shall shortly describe and illustrate this underground electric plant.

The Lime Industry in California.

The increase in population on this coast, particularly within the past half decade, gave quite an impetus last year to the manufacture of lime, which was still further influenced by a higher range in values. Many of the new kilns established have since been discontinued, but they have, so far as ascertainable, been left in such condition that they can be started up at any time the market justifies.

Although deposits of limestone are found in about every county in this State, yet the principal source of supply is in Santa Cruz, where are located the limekilns of the firms of H. T. Holmes & Co. and Davis & Cowell. Those of the former are located near Felton. Their capacity is given at 100,000 barrels a year, with an actual production in 1888 of about 83,000 barrels. The kilns of Davis & Cowell are situated near the town of Santa Cruz. As near as can be ascertained, the output of the kilns in 1888 was about 70,000 barrels. Outside of the above the two firms have kilns in El Dorado county, as follows: Holmes & Co. at Alabaster cave, and one at Antelope canyon, which last year had an output of about 25,000 barrels each. Davis & Cowell have kilns near Auburn and another in Marble valley; in these two the output last year is put at about 25,000 barrels. The product of the Santa Cruz kilns is generally marketed in this city, while that from El Dorado county is marketed in the northern part of the State.

Besides the above firms the I. X. L. Co. of this city have kilns near Felton, Santa Cruz county, that turn out from 35,000 to 50,000 barrels of lime a year. Last year the Rockland Lime and Lumber Company started up their works in Monterey county, 28 miles below Point Sur. They have in use four patent perpetual kilns, with a capacity of 400 barrels of lime a day. As the company did not get thoroughly at work until toward the close of 1888, last year's output cannot be ascertained. The lime from these kilns is marketed in this city. In San Bernardino, at the base of Slover mountain, large quantities of lime are reported to have been burnt last year, but how much is not obtainable. At one time there were 16 kilns in operation, but at the close of the year there were only four. In San Benito county lime is burnt chiefly, if not entirely, for local purposes, quantity and other particulars not known. In Shasta county, near Kennett station, lime is burnt to meet local requirements. In Solano county, near Benicia, lime was formerly burnt, but is not now. In Sonoma county, at Mark West Springs, there is a large deposit of limestone, but which is not now worked. In Kern county, at Pine Grove, Godfrey Poirier has built a kiln and is burning lime. In Antelope canyon, El Dorado county, besides the kilns owned by Holmes & Co. there, a kiln was built the past year by a Mr. Anderson, while still further down the canyon a patent perpetual kiln was built by a firm, name not given. In Santa Clara county the Guadalupe Lime Co. has in operation a patent perpetual kiln; capacity, 60,000 barrels a year. Near Los Gatos, in the same county, there are extensive limestone deposits, which were worked up to 1886 by J. E. Ellis, when work was discontinued but resumed again last year. The output for 1888 was about 120 tons, against about 700 tons in 1885. In Fresno county, near the town of Dunlap, there are two kilns; capacity, 120 barrels a day, actual output not obtainable. The limestone deposit in Hot Springs valley, Alpine county, was not worked in 1888. Work on the limestone deposit at the headwaters of San Mateo creek was not resumed last year.

The outlook for this year is favorable to a large home consumption of lime and a free-shipping movement, but it is claimed by some that with increased production prices will not be so remunerative.

Prospecting.

Judge Baskin says there is a need in Utah of young blood among the prospectors, and a pushing of this valuable branch of the mining industry.—*Salt Lake Tribune.*

The same need is doubtless felt elsewhere. Prospectors are not nearly as numerous as was formerly the case, perhaps because many people feel that the mineral field has been so much narrowed. Yet it should be remembered that there are still large areas of mineral lands in many places on this coast, and that hundreds of mines are annually found. There are men who have followed the business of prospecting for many years, and who no sooner find a claim than they want to sell it and hunt up another one. They have experience in their line, and will not, as a general thing, settle down to the hard work of developing, preferring rather to indulge in their wandering occupation. Most of these men confine themselves to a region with which they are familiar, and work in a desultory way.

There is plenty of room, however, for newcomers. There are areas in the mountain regions which have scarcely been skimmed over. Young, active and energetic men, not "hide-bound" in any particular fads or theories, can take up this kind of work with fair prospects of success. Very little money is necessary, for prospectors' fare is cheap and the living very simple. A summer spent in the mountains in prospecting would be conducive to health and strength, aside from the possibilities of finding a good claim.

It is strange that some of the young men who come to the cities and spend months in search of employment, which, in the end, yields only a bare living, do not strike out for themselves and prospect in the hills and mountains. They spend more money in a couple of months waiting in the city than would suffice to support a prospector all summer. It is true the life is a rough one to some extent, and the luck uncertain. But there are possibilities connected with it which men without capital will not elsewhere find. Even in or near old settled districts mines are sometimes found, and in more remote regions the chances are largely increased. Men without others depending on them for support can well afford to try their chances in the mineral fields of this and other Pacific Coast States.

The Mining Bureau.

The State Mining Bureau receives this year a larger appropriation than ever before—$100,000, as against $60,000 last time. The last Legislature specified that a certain percentage should be spent on work in the field, and this time the same wise provision is made. Of the total $100,000, the sum of $70,000 must be spent in geological or field work. State Mineralogist Wm. Irelan, Jr., has been reappointed for another term by Governor Waterman.

We have no doubt that the publication of the last report of the Bureau had much to do with this favorable legislation. The report was of more practical value to the mining industry than any which have preceded it, and for the reason that the information had been gathered in the mining regions rather than in libraries. The personnel of the assistants was not all that could have been desired last year, but doubtless the Mineralogist and Trustees will profit by experience and obtain other assistants as good as some already employed. There is now money enough to employ good men at good salaries rather than a larger number at small ones. The field can be more carefully studied and available information obtained and put in shape as a practical aid to those engaged in the mining industry.

MORE DEBRIS INJUNCTIONS.—It is stated that the U. S. Government has taken action to stop hydraulic mining on creeks in Shasta county discharging into the Upper Sacramento river. It is learned that a complaint was recently filed in the United States Circuit Court and that Judge Sawyer granted the injunctions which have just been served. Ex Judge A. L. Rhodes of San Francisco is said to be retained by the Government for the express purpose of prosecuting the debris cases affecting navigable waters.

A NUMBER of Comstock miners have left for Trinidad, Sonora, Mexico, where they are engaged to work.

Officials for Alaska.

The time approaches when a corps of new officials is to be appointed for Alaska, the appointees consisting of a Governor, four Commissioners, a Clerk, or Secretary, and a Marshal, who is ex-officio Surveyor-General of the Territory. There is a danger that these places may be filled in part, at least, by Eastern applicants, a thing that for many and obvious reasons should not occur. Instead of this, they should be filled with residents of the Pacific Coast, if not wholly of this State.

In a certain sense Alaska may be considered an appendage of California. The country is largely populated by former residents of this State, the miners being nearly all from here. Her trade and commercial relations are mostly with San Francisco, three-fourths of the vessels visiting that region being dispatched from this port. Whatever industries have been established or improvements made up there have been with California capital. The fisheries, the canneries, the quartz-mills and mining developments are nearly all the results of our enterprise and energy. It would be highly proper, then, that the interests and preferences of our people should be consulted in filling these several official positions.

In the case of Alaska the Governorship and the judiciary are hardly more important than the marshalship, carrying with it, as in this instance, the office of Surveyor-General. The former have their duties pretty well defined by law, their discretionary powers being comparatively limited. But with this purely ministerial officer it is otherwise. In serving the processes of the court he has to deal largely with the rough element incident to these pioneer countries, and is much the better to have had some experience in frontier life. In order to discharge his duties with as little friction as possible, and yet promptly and efficiently, he requires to be a man of nerve—firm and brave, and at the same time cautious and conciliatory. As surveyor, while he should be master of his business, he should also be familiar with the land and mineral laws, the latter already extended to that Territory; and that the entire code relating to the public domain will soon come in force there may be expected.

With a single exception we do not hear that there are any California candidates for civil service in Alaska, though presumably there are a number of aspirants to the places to be filled there. For the position of Marshal, Francis Tagliabue is, we are informed, an applicant. Concerning his fitness for the office this may be said: Mr. Tagliabue, now a resident of San Francisco, came to California over 30 years ago, being then a very young man, who had just finished his school training for surveyor and civil engineer.

In 1858 he went to British Columbia, and for one year was engaged on the new wagon-road built by the local government for connecting the Lower with the Upper Fraser river, a costly and important work. Returning to this city the following summer, he proceeded at once to Western Utah, where he made his home for the next 15 years, and during which time he filled the following positions: Assistant Marshal for the new Territory of Nevada; county surveyor, first of Lyon and afterward of Lander county, under appointments by Governor Nye, the "gray eagle" of Republicanism. Later on, Tagliabue was elected county surveyor of Nye county and afterward of White Pine county, discharging the functions of the office always to the entire satisfaction of his constituents. In 1864 this gentleman was a member of the Constitutional Convention that framed the fundamental law adopted by the State of Nevada on its admission to the Union.

He has already made several visits to Alaska, and owns what are supposed to be valuable mining and other interests there.

Though so long on the "borders," Mr. Tagliabue has never been involved in any difficulties, personal or professional, his official life having been little disturbed by the scenes of turbulence and strife by which he has so often been surrounded. With such qualifications and such an experience, it might reasonably be expected that this gentleman would make a good marshal for the outlying and remote Territory of Alaska.

IT is stated that the best mine at Harqua Ha'la, A. T., has been sold to George Hearst of California for $200,000.

Settling-Vat for Trough Lixiviation.

In continuing the descriptions of the appliances used in Hoffmann's trough-lixiviation process which have appeared in recent numbers of the PRESS, we give on this page cuts of the settling-tank. Fig. 1 represents the vertical section, Fig. 2 the horizontal view, and Fig. 3 the front view of a settling-tank arranged for sluicing. Fig. 4 is a detail of *F* in Figs. 1 and 3. In the center of the bottom is the discharge opening, six inches in diameter. The cast-iron discharge tube *K* of the same inside diameter, tightly fastened to the outside of the tank-bottom, corresponds with the discharge hole. The lower end of the tube is at right angles with the upper end, and provided with flange *o*. The valve *m*, which is provided with a rubber gasket, can be pressed tightly against flange *o* by turning the wheel *F*. Flange *o* and valve *m* are made of brass. Fig. 4 shows in detail the construction of wheel *F*. Around the discharge opening, and fastened to the bottom of the tank, is the wooden polygon *v*, in which is cut the groove *p'*. Around the inner periphery of the tank, and high enough to give the filter-bottom an inclination of at least three-fourths' inch to the foot, is the groove *p*. Fig. 2 illustrates the construction of the filter-bottom, which is made in section.

The filter cloth is well fastened, and kept in position by driving tightly a rope into the grooves *p'* and *p*. The air-escape pipe *d*, which reaches to the rim of the tank, enters the latter close under the filter bottom. A piece of hose is fastened to the upper end, and can be closed by a hose-clamp. In Fig. 3, *q q* are solution outlets; *s*, filter outlet. Connecting pipes *g* and *h* (Figs. 1 and 3) have, like the discharge tube *k*, to be well coated with asphaltum varnish. In the same figures, *z* is the water pipe; *n*, the central hose, which reaches down into the discharge tube *k*, where it has to remain during the process of charging. This hose ought to be very stiff. Before charging the tank the discharge pipe is filled with water through the central hose, in order to keep the latter filled with water, which will prevent the inside of the hose from being obstructed by ore. In the base-metal department the central hose has to be connected with the water and solution pipe to allow the application of either, while in the silver department they need only to be connected with the water pipe.

When a tank is ready to be discharged, the wheel *F* is turned, and thus the valve *m* pulled back. The water is injected through the central hose, while the latter is gently moved up and down. The stream undermines the tightly-packed sand and causes a continual caving-in, until a funnel-shaped opening is made through its depth to the surface. Then several streams are made to play on the top, while the central hose, with checked stream, is left in position to avoid obstruction of the discharge pipe by a too sudden rush of sand.

The central position of the discharge opening and the funnel shape of the filter permit a quick and clean sluicing. The pulp leaving the discharge tube enters the sluice-trough *t* underneath the tank, which leads to the tailings-trough *u* in the silver department, or to the silver-leach trough in the base-metal department. The charge being sluiced out, tank and filter have to be well rinsed, the valve of the branch pipe *a* is opened, and the adhering sand washed off from flange *o* and valve *m* by the double sprinkler *w*. Then the discharge valve is closed again, and the tank is ready to be connected with the other tank. In Figs. 1 and 3 *y* represents the silver-leach trough; *b*, the intersecting-box above the tank; and *i*, a short hose made of duck.

SETTLING TANK ARRANGED FOR SLUICING IN TROUGH LIXIVIATION.

Chrome-Iron Ores.

We have received several letters of inquiry during the past week concerning chrome-iron ore. This ore is found in several counties of California, especially in San Luis Obispo, Alameda, Del Norte, Placer and Shasta. The production of California runs from 2000 to 3000 tons a year. Chromium is not now mined elsewhere in the United States, though some has been worked in Maryland and North Carolina. Large importations come from Turkey and Asia Minor. The low price which must necessarily be received in this State for material which is to compete with foreign importations in the Eastern market has discouraged mining here. The mines here are seldom carried far below the surface. The deposits found are irregular in nature, the ore being in bunches more or less scattered. It occurs in no regular ledges as does quartz, so the extent of supply is always uncertain. The majority of openings made for chrome ore in California have yielded comparatively small amounts of ore. The San Luis Obispo and Del Norte deposits are the best thus far found.

These ores are shipped to Baltimore and Philadelphia, where potassium and sodium bichromate are manufactured from them. Some is also used in the manufacture of chrome steel used in making safes and machine tools. The bichromate is used in calico printing. It is also made into the pigments chrome yellow and chrome green. A small quantity is used in electric batteries. Most of the chrome ore is worked up in Baltimore.

With lower freight rates the chrome-iron industry of this State would be in a much more flourishing condition, and, were the tariff higher on foreign material, California would soon produce all that the United States requires. As it is, however, production is limited, since only the best deposits are worked, and there is not very much money in the business. The duty is $3 per ton. The last U. S. Geological Survey report credits California with a total annual product of chrome-iron ore of 3000 long tons, worth in San Francisco $40,000. The cost of mining chrome ore in California and shipping to Eastern ports ranges from $17.25 to $20.95 per ton in different localities.

THE Occidental Mining Company has closed a contract for the erection of a 20-stamp mill on a site convenient to the mine, with concentrators attached, the whole to cost $45,000, and to be in complete running order by July 1st. The Occidental has an area of many thousand tons of ore stripped on the upper levels ready for extraction. This ore will all show a value of above $30 per ton by battery sample assays, and can be run out through the various tunnel levels to the new mill without entailing the cost of expensive hoisting.

SHOP NOTES.

A Profitable Foreman.

Every manufacturer that employs a number of workmen requires the service of a competent foreman or overseer to look after the help.

No doubt that a great deal more money could be made if the proper man's service for the place was secured. I presume there are a great many foremen to-day in our shops that are unprofitable, but hold their positions simply because they are good workmen and reliable judges of work. These qualities are necessary, of course; but, nevertheless, few foremen possess the qualifications that are the make-up of a practical "boss." And they usually lack the most essential one—the gift of command. Without it success never becomes a realization, only a dream of the ever future. A man in a position of this kind should be a student of human nature and court the courtesy of his subordinates. The benefits of this are clearly demonstrated as we turn back the pages of history and see them dotted here and there with a general's name that has made a success as a foreman of his army.

If Washington had not had thorough control of his soldiers they would have deserted him at Valley Forge. If they had not respected him, his pleadings would have had little weight, his command would have been ignored. Upon the Emperor Napoleon's return from Elba his former followers flocked around him ready to lay down their lives for his glory, proving their fidelity to him and showing his command over them. Cæsar overran the Roman Empire, overthrew his rival and conquered all before him, simply because he commanded the respect of his soldiers, thereby commanding their will to such an extent that they were ready to suffer death at his dictation. And so it is with a foreman. He should have his help at his command—have them interested in their work—and to do this he should keep in mind the fact that *to command a man's respect is in a certain degree to command his will.* That is the secret of success, in my mind, to any one that has charge of men.

If the workmen dislike a foreman on account of pomposity or some similar reason, they are not apt to do more than they are really obliged to. A man gets disinterested in his work and then proves an unprofitable hand. He is then discharged, a new man hired in his place; he has to get acquainted with the shop, and for a time may not be worth his money, causing a loss to the firm. By the time he gets the "ropes" learned, some one else gets through for the same reason, and another loss is made; and so it goes during his stay. A foreman makes a mistake when he shows his authority in a self-conceited way. A man of that description cannot get as much work from his men, and they are constantly leaving him. A little courtesy often goes a great way toward winning the good-will of a man, and it is human nature for a man to please those he likes. A thorough, práctical workman that will treat the help with the same respect that he would demand, is the man for such a position every time.

No Such Thing as Perfection.

The mechanic who thinks he has arrived at perfection may be written down as an ass. There is no such thing as "perfection" in the mechanical arts, and the man who claims to be a complete and finished mechanic knows in his heart he claims that which does not belong to him, and he will soon discover his vanity, for his fraudulent pretenses do not deceive the employer to any great extent. Blow and bluster will not make good work or pass for efficiency, and the man who uses that sort of weapons seldom deceives an employer. "I never employ a man who knows it all," said a large contractor to us the other day. "Give me a modest, neat-looking man," he continued, "and I'll hold you a dollar he is a good workman and one that may be relied upon; though, of course, that sort of man seldom comes in search of employment. Bragging fellows, who state they can do anything from dressing a board to designing a cathedral, are quite numerous, and may be had at any moment." Doubtless this is true, but it does not argue that there are not many of the modest workmen. There are plenty of them, good, reliable fellows—fellows that seldom or never have need to seek employment. They are always engaged. Most of them own their homes, are intelligent chaps, models in their own neighborhood, best of citizens, have neat, thrifty wives and healthy, happy children, and their country is proud of them, for it understands that they are towers of strength and bulwarks of true freedom. It is not from this class anarchists or noisy demagogues are drawn; they do nothing until they have first considered the results, and all their actions are tempered with wisdom; hence their ability to become good mechanics.—*The Timber Worker.*

A GOOD RULE TO FOLLOW.—All who have made any marked success in any calling or profession have made it the rule of life to be always in advance of their enemies, so as to meet them in battle when they least expected them. This had much to do with their success. They led the age by always being in advance of it. This rule should be applied to trade as well. Be the leader in your line; keep ahead instead of being behind. Do the thinking yourself, and not leave it to others. Exercise your own judgment in all things. The man who lays his plans carefully, and considers well everything that relates to or concerns his business, and relies upon himself for directions, always succeeds. The one who puts off for another time that which should be done to-day, who depends upon others for suggestions and advice, rarely, if ever, succeeds. Strong individuality, self-reliance and promptitude of decision mark the pathway of the successful merchant. When united with a clear head, quick eye to look ahead before making a move, they achieve success, create wealth, honor, and quicken the life of trade and commerce.

Belt Speed and Power.

We say that the amount of force transmitted by a belt of given width depends upon the speed of the belt; that if 600 feet per minute will give ten-horse power, then 1200 feet will give 20-horse power, and that if we only run the belt fast enough we could drive a whole machine-shop with a three-inch belt. This is a correct statement and may not appear at all difficult of comprehension, but unless we bear in mind that the increase of velocity must be accompanied with an increase of leverage, we may make a mistake.

In running a lathe with the belt on the slowest belt-speed, taking all the cut it will carry, suppose that we stop the feed, withdraw the tool and then change the belt to the next faster step on the cone, then we will have increased the speed of the belt; but if we undertake the same cut again, the belt will not carry it at all, because, although we have increased the speed of the belt, we have not increased its leverage. But if we now put in the back gearing, the leverage will be increased and the belt will carry a heavier cut than it did in the first instance.

Again, suppose the belt from the line shaft to the countershaft be too narrow for its work, we cannot increase its efficiency by running the line shaft faster; for, although that would make the belt run faster, it would not increase its leverage, or, in other words, it would not change its speed in relation to the speed of the work.

To make the narrow belt do an increased amount of work, or do its work easier, we must put a larger pulley on the line shaft, and also increase the size of the pulley on the countershaft in the same proportion. This will give the belt a greater distance to travel in the same time, and will give it a greater leverage, while the lathe and the line shaft will both run at the same speed that they did before the change of pulley; but the efficiency of the belt will be greater.—*Western Machinist.*

WORTH OF PERSEVERANCE.—In any line of business, says the *Scientific American*, the man who uses reasonable economy and has the ability to give fair management, and the perseverance to hold on, will in a great majority of cases make a success; while, on the other hand, the one who rushes into whatever he has undertaken with a spasmodic effort to win all at once, as a rule wastes his energies and often fails for sheer want of perseverance. The man who starts in to do a day's work, and attempts to do as much in one hour as ought to be done in two, will usually find it necessary to take a rest, and while he is resting will lose valuable time which he evidently feels that he ought to make up, judging from the spasmodic efforts he will make when he starts in to work again. But at night the man who works steadily and perseveringly will be found to have accomplished the most, while usually he will be found in a much better condition to commence again the next day. So it is in business. The man who is constantly shifting about is always making a change at the wrong time, when a little perseverance would have brought him through all right. In all lines of business there are fluctuations, ups and downs, and in order to succeed we must persevere. It is when the odds seem against us that it seems the most important to persevere.

A LABOR UNION VIEW OF PIECE WORK.—An organization composed of Pittsburg iron-molders recently refused to arrange with the employers to work by the piece, claiming that such an arrangement would be a violation of a rule of their union. The result was that large contracts were driven from Pittsburg and sent to establishments where the men were willing to adopt the method refused by the Pittsburg molders. In commenting on that fact the *Western Manufacturer* expressed the opinion that the policy of the Pittsburg workers was a most unwise one. The *Labor Tribune* apparently took the same view of the matter, as is shown in the following editorial clipped from the latest issue: "There should be no cast-iron rules governing in such matters. They work too often to the disadvantage of both employers and employes of union establishments. Besides, it has not been many years since piece work was regarded as the fairest and best all around. All tonnage work of the mills and mines is piece work, and the system is infinitely better than day wages. So is piece work wherever it can be employed, for it gives the industrious and skillful man his earnings, while the other way handicaps him by strapping the unskillful and not overly industrious on his back."

STEAM BOILER NOTES.

Improved Steam-Boiler Furnace.

The Hoperaft Furnace Company of Walbrook, London, is the proprietor of a new steam-boiler rotating furnace, which is self-feeding, self-maintaining and self-discharging. Only small or slack coal is used.

The construction of the furnace is described by the English correspondent of the *American Manufacturer* as follows:

The fuel, which is small coal, is charged into a hopper in front of the furnace, which is inclosed on account of the forced draught. From the bottom of the hopper a pipe rises with a gentle curve to the outside of the furnace. Inside this tube works an ingenious vertebrated archimedean screw, by which the coal is slowly fed upward into the center of the body of incandescent fuel in the grate. The grate, which is circular, consists of concentric rings of cast iron, with air spaces between them, and it slowly rotates on its axis, which is inclined toward the bridge at a slight angle. A supplementary grate is fitted beyond this, and receives and automatically discharges the clinkers, which are continuously delivered on to it by the circular grate. The inclination thus given to the grate beneficially directs the radiant heat of the fire toward the heating surface of the boiler, and promotes the uniform and constant distribution of the fuel, which tends to fall toward the lower level and is gradually elevated to the higher level in the course of the revolution of the grate.

The products of distillation—otherwise the smoke-producing constituents of the coal—having to pass up through the incandescent fuel on the grate, become highly heated, and, meeting with streams of atmospheric air which are also being forced through the incandescent fuel on the grate, ignite, producing brilliant flame. The residue of coke is burned on the grate, and forms the incandescent fuel which renders the process constant and regular so long as the furnace is at work, and so long as coal and air are supplied in due proportions.

The forced draught is supplied by a Sturtevant fan driven by a small auxiliary engine, which also drives the gearing for revolving the grate, the speed of which is about one revolution in five minutes. The air supply being in direct communication with, and controlled by, the coal feed, the relative proportion of air to coal remains practically constant whether 10 pounds or 40 pounds of coal are being consumed per square foot of grate surface per hour.

The trials made with the Hoporaft furnace prove that slack can be burned without smoke and at a saving of from 40 to 50 per cent, the engines indicating the same horse-power as when best Welch coal is used, under the continuous action of a steam blast in the fuel.

ECONOMY IN STEAM BOILERS.—Mr. Robert Scott of Newcastle-on-Tyne has constructed a new boiler, built upon new principles first experimentally utilized by him in the spring of 1886. At a recent trial common duff coals were used, costing 2s per ton, and with these a splendid fire was produced. The boiler with the fire-grate system would represent about 16-horse power, but, owing to the rapid generation of the steam under Mr. Scott's method, he claims that it is over 30-horse power. The inventor states that the system will save upward of 40 per cent in quantity of fuel, but, as the most inferior kinds of coal can be thoroughly utilized, the saving in money value varies from 40 to 75 per cent, according to the kinds of fuel used. An important feature of the system is the almost total absence of smoke, due to the completeness of the combustion; no ashes are produced; everything is consumed except the clinkers. Stoking and cleaning the furnace are easily accomplished. Mr. Scott is conducting further experiments, by which he hopes ultimately to make his process quite smokeless.

A NEW BOILER ARRANGEMENT.—A Russian engineer has arranged the fire tube of a horizontal boiler in such a manner that it may be removed in its entirety without any disturbance of the boiler end. The fire tube is of conical shape, and it has an approximately elliptical cross-section. Flanges are formed upon the ends, by means of which it is secured to the body of the boiler, the back flange on the small end of the fire tube abutting against the rear end of the boiler, and the larger end abutting on the outside of the front end. The opening in the front of the boiler for the admission of the fire tube is of sufficient size to allow of the insertion of the back flange, and after the bolts have been unfastened, the fire tube may be withdrawn without disturbing the body of the boiler itself. The fire tube is provided with vertical cylindrical tubes of small diameter, and by the oval cross-section of the fire tube a greater number of these cross tubes may be inserted than has been hitherto possible, and the heating surface increased in consequence.

THE WEAR AND CARE OF ENGINES.—Engines are subjected to two different kinds of wear. One is due entirely to the unavoidable friction of the working parts on each other; as, for instance, the brasses on the pins and journals, crosshead brasses on their guides, piston rings in the cylinders, eccentric straps, piston rods, valves, valve stems, packing, etc. The other is due to a nut, bolt, or key working loose, a brass working loose in a strap, or undue strain working a frame loose at a joint. An engine is generally designed so as to provide for the kind of wear first named, as it is well known and to be expected, and may go on to a considerable extent for quite a period of time without materially injuring either the engine or its working. But the second cannot be either expected or provided for, but when once discovered, it should be remedied at once. Experience has shown, says the *Safety Valve*, that the engine that runs smoothly, does its work silently and economically, is almost invariably a clean engine; the engine-room is clean, and where you find a clean engine you will generally find a competent engineer. The engine that pounds and groans as it does its work is nearly always dirty, in fact, filthy, is expensive, a nuisance, and is usually to be found in charge of a person whose chief concern is quitting-time and the weekly envelope. The piston of a steam engine is not at first sight a likely part to give way through explosion. But there are cases on record where hollow pistons, on being heated for removal from the rod, have unexpectedly exploded. Such explosions of hollow cast-iron pistons have recently been the subject of special attention in France, the fact appearing that no less than five such explosions have occurred in French workshops during the last 20 years in reheating these pistons. In examining into the interior of a piston that had been in use for 11 years, there was shown the existence of a brown substance containing fatty matter, oxide of iron, peroxide of iron, and carbon. From this it was supposed that a certain quantity of water had been forced into the cavity in service, either through the iron or through the imperfection in the plugs with which the original core-support cavities were filled. This water, in forming oxide of iron, set free its hydrogen, which filled the piston cavity, and as the recombination of this hydrogen with the oxygen at a low red heat would have the effect of producing such an explosion, it is suggested that this result may be prevented by being tapped before reheating.—*Western Machinist.*

FIRING BOILERS.—A correspondent of *Power* writes that paper as follows: "Last year I ran for three months wetting my coal enough to thoroughly dampen it, then threw it on the front of the furnace for a few minutes, broke it up, let it lie a few minutes longer, then shoveled it back and threw a fresh lot on. Then I tried firing one side of the furnace, let it lie a few minutes, then broke it up, and fired on the other side. I found this an advantage. It reduced the amount of smoke and I thought made a better fire. In both these cases I tried the coal both wet and dry, but could perceive no difference. I next tried throwing on a shovelful at a time as the fire needed it, and not breaking it up at all, except when I clean, which is once a day. Now you see very little smoke, and I think some saving in coal. And if my boiler was properly set (it being only about 20 inches from the grate bars) for burning soft coal, I do not think there would be any smoke. I am now running about the same amount of coal I did last year, and doing pretty nearly double the work, so there must be some saving by this mode of firing. And it is certainly a great saving in work, for all engineers know there is not much fun in slicing up and shoveling back a white hot fire."

ALUM IN BOILERS.—In regard to the use of alum in boilers, a correspondent says: "Alum of all kinds is a solvent for iron, dissolving it in appreciable amount. Ammonia alum is probably the most active, but potash alum is quite ready to attack iron. The chance of an accumulation of alum in a boiler is, therefore, very undesirable, and cases are not infrequent where the action is quite marked. In the case of a water containing much organic matter, as slaughter-house refuse or animal sewage, if alum was used in only just the right amount, the advantage might be marked in purifying the water, but the danger is that an excess will be used. Alum is itself a slightly acid salt, but the probability is that in the boiler it decomposes, the sulphuric acid in it removing the scale and eventually attacking the iron."

TRIPLE EXPANSION.—In discussing a paper on triple-expansion marine engines, recently read before an English engineering society, it was pointed out that in two ships alike in every respect except that the one has two-crank and the other three-crank engines, the consumption of coal per indicated horse-power is precisely the same, but that the three-crank engine drives its ship half a knot, or five per cent faster than the two-crank engine. This is a very important point, and one which has not been sufficiently dwelt on by marine engineers, because in discussing the relative merits of the two and three crank engine it has been practically limited to comparing the consumption of coal per indicated horse-power.

BOILER TESTING.—An "engineer" in charge of a boiler in New York, which he was operating without the required license, recently undertook to test his boiler with cold-water pressure from the hydrant. He had been running with 80-pounds pressure, at least that was the story the gauge told, but when he got the 60-pounds hydrant pressure on, he blew the tube sheet out. It was rather suggestive of what might have happened before with steam on; but then he worked cheap.

McAFEE & BALDWIN,

REAL ESTATE AGENTS AND AUCTIONEERS, - - - - - 10 MONTGOMERY STREET, SAN FRANCISCO.

AT AUCTION!

THURSDAY, FRIDAY AND SATURDAY,

MARCH 21st, 22d AND 23d, 1889, AT 2:30 P. M.

BY ORDER OF J. B. HAGGIN, ESQ.

We will sell peremptorily, without limit or reserve, on THURSDAY, FRIDAY and SATURDAY, MARCH 21st, 22d and 23d, 1889, at the hour named, in the city of

BAKERSFIELD,

KERN COUNTY, CAL.

IN SUBDIVISIONS OF 10, 20, AND 40 ACRES EACH, ABOUT

7000 ACRES

OF FRUIT, VEGETABLE AND ALFALFA LAND, WITHIN ONE TO SEVEN MILES FROM BAKERSFIELD, BEING PORTION OF THE

HOP RANCH, COTTON RANCH, JEWETT RANCH,

AND OTHER RANCHES,

ALSO, CHOICE RESIDENCE AND BUSINESS SITES IN BAKERSFIELD.

This is the initial offering, and the commencement of the subdivision of the large possessions of MR. J. B. HAGGIN, in Kern County. The property embraced in it includes some of the finest lands in the county, as all well-informed residents of BAKERSFIELD will testify. About 2500 acres of the land offered is in alfalfa, and can be rented or otherwise utilized to yield a large income and a high percentage upon a valuation of from $150 to $200 per acre. Other portions of the offering are used for vegetable and garden purposes, while the balance is composed of land rich and fertile, awaiting only the industrious settler to demonstrate its great adaptability to fruits and the products of this wonderfully prolific soil. A large portion of these lands lie along and adjacent to UNION AVENUE, which as at present dedicated extends from Kern river south through BAKERSFIELD, a distance of ten miles, and which is one hundred and fifteen and one-half feet in width. The other tracts are reached by excellent county roads leading direct to BAKERSFIELD.

WATER FOR IRRIGATION.

The lands to be sold are amply supplied with water for irrigation, from the Kern Island Canal, at rates now the lowest in the State, and *fixed and regulated by the County Board of Supervisors.*

UNUSUALLY LIBERAL TERMS.

TERMS OF SALE: Only one-fourth Cash. Balance in 1, 2, and 3 years, with interest at the rate of seven per cent per annum. TITLE PERFECT.

SPECIAL EXCURSIONS.

To enable all to participate in this important event, we have made arrangements with the Railroad Company by which we are enabled to offer special round-trip rates from all points to BAKERSFIELD, between SAN FRANCISCO, SACRAMENTO, SAN JOSE, STOCKTON and LOS ANGELES, as follows: SAN FRANCISCO, SACRAMENTO, STOCKTON, SAN JOSE, and all intermediate points, to Bakersfield and return,

$9.50 ROUND TRIP TICKETS ONLY $9.50

$9.50 ROUND TRIP TICKETS ONLY $9.50

AND CORRESPONDING RATES FROM ALL POINTS BETWEEN LATHROP AND BAKERSFIELD.

From Los Angeles to Bakersfield $5.50 ROUND TRIP TICKETS ONLY $5.50

And corresponding rates from all points between Los Angeles and Bakersfield.

TIME TABLE.

Tickets will be good on trains leaving San Francisco March 20th and 21st, at nine o'clock P. M. and on March 21st, at half-past eight o'clock A. M., and on trains from Sacramento, Stockton and San Jose connecting therewith; and from Los Angeles on train leaving March 20th, at half-past ten o'clock P. M.

RETURNING, tickets will be good on all regular trains, leaving Bakersfield March 22d, 23d, 24th and 25th, 1889.

GRAND BARBECUE.

Vehicles will be at hand to convey excursionists over the property to be sold, starting at half-past ten o'clock A. M. of each day.

On Thursday, March 21st, there will be a Grand Barbecue, at about one o'clock P. M., in the Grove at Bakersfield, to which all will be welcome.

Railroad Tickets will be on sale at the offices of the Company, and at the office of McAFEE & BALDWIN, 10 Montgomery street, San Francisco, where sleeping-car accommodations can also be arranged for.

Maps and diagrams will be ready for distribution in due time. For further particulars, apply to

McAFEE & BALDWIN, REAL ESTATE AGENTS and AUCTIONEERS,
10 MONTGOMERY ST., SAN FRANCISCO.

NEWHALL'S SONS & CO., Auctioneers,
225, 227 Bush Street, San Francisco.

LAND DEPARTMENT OF J. B. HAGGIN,
L. C. McAFEE, C. BROWER, Managers,
Bakersfield, Kern County, Cal.

About Obtaining Patents.

Patents are Virtually Contracts.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, in order that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented to another. This requires an exhaustive search among all the patents in the class to which the invention relates. If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of $5 for the examination, a verbal or written report showing definitely wherein his invention has been anticipated, thereby saving him further expense and perhaps much time, anxiety, etc.

To avoid all needless delay, however and secure patents at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with $15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately and forwarded to the inventor for his signature. When he receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order or express receipt for our own fee. The case will then be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps.] When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of $20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give up a case so long as there is a chance of obtaining a patent. The Agency charge, including drawings, rarely exceeds $40, and for this we do all we can without appealing the case.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are more satisfactory to the Patent Office than the old cumbersome system of storing up an immense bulk of countless models.

Drawings or sketches, sufficient to illustrate the invention clearly, with a description that will enable us to make a full set of perfect drawings for the Patent Office, is all that we require. A model will answer our purpose as well, however, in cases where the inventor can more easily furnish it.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention, while in reality it may be of great value, and would meet with ready sale had it been skillfully, completely and artistically portrayed. In all cases prepared by us the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken to have the invention fully and clearly shown by different views, so that the improvement will be readily understood by the Examiners in the Patent Office, and comprehended by the public when the patent is granted.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & Co. has edited and published the MINING AND SCIENTIFIC PRESS continuously since 1860, a period of 28 years. Few agents, who are still engaged in the business, have had so long-extended practice in patent soliciting. The members of the firm give personal attention to the applications intrusted to their care; and their familiarity with inventions and with local affairs in the Pacific States and Territories, enables them to understand the wants of inventors on this coast more readily and thoroughly, as we believe, than any other agents in America. Thus there is saved a great deal of the time which ordinarily —when distant agents are employed—is wasted in preliminary writing back and forth.

This happy-combination of long business experience together, and wide connections, has placed our firm in a position unquestionably most fortunate for affording inventors prompt and reliable advice, and the best facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation best calculated to widely inform the class of readers especially interested in the subject of his invention.

Caveats.

A Caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is, that it entitles the caveator to receive notice, for a period of one year, of any application for a patent subsequently filed, which is adjudged to be novel and is likely to interfere with the invention described in the caveat, and the caveator is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from $10 to $20. The Government fee is $10 additional.

To enable us to prepare caveat papers, we require only a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves or for them by other agents) and desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

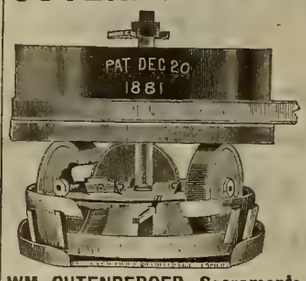
Inventors doing business with us will be notified of the state of their application in the Patent Office whenever it is possible for us to furnish such information.

DEWEY & CO.,

Patent Solicitors, Office of SCIENTIFIC PRESS, 252 Market St. Elevator entrance, No. 12 Front St., S. F.

GEO. H. STRONG. W. B. EWER. A. T. DEWEY.

GUTENBERGER'S ROLLER ORE CRUSHER.



Crush 8 to 10 Tons per Day.

PORTABLE and DURABLE.

WEIGHT, 4 TONS.

It is a Full Fledged Quartz Mill without Gearings, Cogs or Pulleys.

Power applied direct. Works Ore at Low Cost. More or less weight on Crushers as desired.

Very little friction. Beats other machines in reducing and amalgamating ore, and costs less. All who have used this mill recommend it highly. Splendid for low-grade ore on account of low cost of working. The first ore crusher used in Durango, Mexico, was built at my shop in Sacramento, and under my patent.

☞ Any Infringement on this Patent will be prosecuted to the full extent of the law.

WM. GUTENBERGER, Sacramento Foundry, corner N and Front Sts., Sacramento.

H. D. MORRIS.

VALUABLE BOOKS ON MINERALS AND MINING.

A PRACTICAL MANUAL OF MINERALS, MINES AND MINING; comprising suggestions as to the localities and associations of all the Useful Minerals; full descriptions of the most effective methods of both the qualitative and quantitative analyses of each of these minerals, and hints upon the various operations of mining, including Architecture and Construction. By Prof. H. S. Osborn, LL. D. Illustrated by 171 engravings. Svo. 367 pages. Price.....$4 50

☞ A descriptive circular giving the full contents of the above book sent free to any one who will send his address.

A TREATISE ON METALLIFEROUS MINERALS AND MINING. By D. C. Davies. With 148 illustrations. 12mo, 432 pages. Price..$5.00

MINE DRAINAGE. By Stephen Michell. Svo, 277 engravings. Price.....$6.00

A TREATISE ON EARTHY AND OTHER MINERALS AND MINING. By D. C. Davies. With 76 engravings. 12mo. Price.....$5.00

THE PROSPECTOR'S HAND BOOK. A Guide for the Prospector and Traveler in search of Metal-bearing or other valuable Minerals. Illustrated. 12mo. Price.....$1.50

MINERALOGY SIMPLIFIED. Easy Methods of Identifying Minerals, including Ores, by means of the Blowpipe, by Flame Reactions, by the Spectroscope and by Humid Chemical Analysis, based on Von Kobell's Tables for the Determination of Minerals, etc. By Henri Erni, M. D. Illustrated. 12mo. Price...$3.00

UNDERGROUND TREASURES; HOW AND WHERE TO FIND THEM. A Key for the Ready Determination of Minerals within the United States. By James Orton. Price.....$1 50

☞ The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

☞ Our New and Revised Catalogue of Practical and Scientific Books, 34 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

FOR SALE.

One 10x13 inch Clayton Belt Air Compressor.
Three 3-inch Sergeant Drills.
Three 5-ft. Double Screw Drifting Columns with Arms.
One 4-ft. Single Screw Stoping Bar.
One Set Sharpening Tools.
About 1500 pounds Drill Steel.
One 8½x13 ft. Air Receiver.
One Tustin Pulverizer, with new wearing parts, such as Rolls, Grates, etc.

The above are in first-class condition and will be sold cheap. For price apply to the

PAYMASTER MINING CO.,
Yuma, Arizona Territory.

Practical Treatise on Hydraulic Mining.

BY AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdys, rockers, undercurrents, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, $5, post-paid. For sale by DEWEY & Co., Publishers, 220 Market St., San Francisco.

Lower California Gold Mines.

The Excitement About the Santa Clara Placers.

The Lower California gold excitement still continues, and hundreds of people are now on the road there to add to the numbers already on the ground. The steamers from San Diego are crowded with gold-hunters and the road from Tia Juana is lined with teams loaded with provisions and men on their way to the mines. The trains from Los Angeles southward are crowded and the excitement seems to have been imparted to all classes of people in the southern part of the State.

Although partly placer ground, it is now known that this is not a poor man's camp, as provisions and all necessaries are very high in price. Late news from there warns poor men to keep away. The rich placers will, it is said, last but a few weeks, and though considerable gold has been taken out, many persons agree that the accounts have been much exaggerated.

It would be impossible in the space at our disposal to publish all the statements made concerning the mines. In our Mining Summary, on another page, are given the views of several correspondents; and we print also a map of the district and the routes thereto, with a picture of Ensenada, the Mexican port where the California steamers land.

Judging from the columns of matter published in the San Diego papers, half the population of that section must have left or be about to leave for the mines. It is claimed by some of these papers that the placers and quartz leads are the richest ever found on this coast. During the past few weeks nuggets were searched for on dry ground with some success, several hundred holes having been dug.

The section where the mines are found has long been known to be rich in gold, and has afforded for many years a living for 100 or more Mexicans. The recent rich spots found have caused the excitement which has been increased by the highly-colored published accounts.

Three quartz mines, with good prospects, have been found within six or eight miles of the placers. The Mexicans and Indians are not working with water, but are scraping around in the crevices in the rock. They dig out a large hole to bedrock, then scratch in the dirt with spoons for nuggets. On the other hand, the Americans use a rocker and gold-pan, or, in the absence of a rocker, the pan alone. Water is not plentiful, and before long drywashers will have to be used.

Mr. F. J. Shemler, who visited the camp a week ago, says that the gulches are nothing more than water-courses, which are perfectly dry in the summer, but in the winter are often raging torrents. The beds of these streams are composed of black sand, gravel and bowlders washed down from the mountains. The most successful miners are Mexicans, who simply work among the bowlders, gathering the coarse gold, and the majority are making money. The gold found in the gulches is either float or scale gold, and there is every indication that it has been washed from the mountains at the head of the gulches. A number of quartz claims have been located on either side of the creeks, but the most important ledge has been discovered at the head of American gulch, and located by miners in the employ of a San Francisco mining company. Eight fine specimens show good samples of wire gold, while the remaining ones are fine-milling ore. The veins thus far opened up show good milling ore to a depth of ten feet, the ledge having a pitch of 42½ degrees. The camp is fast filling up with a class of men who have just about money enough to get into camp with, and as they know nothing about mining, they soon become discouraged. In his opinion there are good mines in the new district, but the precious metal will be found in the mountains in gold-bearing rock, which it will take capital to work. The first money spent must be for water, and after this is done stamp-mills will have to be erected. He expects to return to the mines at once, secure a water-right for his company, and then erect a mill and commence work. Mr. Shemler advises all poor men and those not practical miners to remain away, at least for the present, as provisions are scarce and every inch of ground is taken where there is the least prospect of securing gold in the placer diggings.

A party which returned from Ensenada to Los Angeles on the 12th say that the whole excitement has been arranged by colonization and railroad companies. There is no doubt, however, about gold having been found in both placers and quartz. There is little doubt, too, that the richness of the district has been exaggerated. Miners who have returned this week bring discouraging reports and say that in a few days the homeward pilgrimage will commence. A correspondent of one of the San Francisco dailies writes that the majority who are leaving the camp have not given it a fair show. "They came with enthusiasm, and for a few hours worked like beavers, but not turning up gold like a farmer's plow turns up the sod, sat down and declared that the camp was no good and all that was written about it false. There are two long gulches bearing gold from end to end. I have discovered within the past few days that Mexicans were working the mines months before the strike was known to the outside world. Most of them are big paying claims. I know several Mexicans who are taking out on an average $50 a day, while a great many work pretty hard and do not average $5 a day. I think it safe to say that there are 200 men with picks, shovels and pans skirmishing all over the camp who do not make salt. These people are 'coyoters,' who work a claim about half-way to bedrock and then desert it. There are good claims and barren ones adjoining each other, and many hard-working men dig away for days without striking color, while their neighbors are panning out pay dirt right along."

The indications from the gold-fields are that the country is overrun with people, the placer area is too small to warrant a rush and ledge mining too slow for anxious people. The consensus of opinion of those who have returned is that the output is confined to quartz leads, it is not a poor man's camp, and that too many people are there now. Water is getting scarce and the Mexicans are corraling everything. Other reports, which are just as encouraging as before, make it difficult to get at the truth.

Mr. Harry N. Cannon, who is at the mines, writes to the *Examiner* of the 13th that the telegraphic report stating that $400 had been taken out by one man in a day is incorrect, nor, says he, has any man taken out $75 or $80 in a day. There is room for only about 100 men to work in the placers, and they make fair wages while water lasts. But in a few months there will be no water, and then no work can be done.

Judging from all the conflicting reports, it appears that there is placer ground, but not very much; that water is scarce and will be scarcer; that some of the quartz veins found give very good indications; that too many men are there already; that provisions are expensive, and that while the camp may do well enough for men with money, it is no place for poor men to go.

Legislative.

The Assembly bill appropriating $160,000 for additional jute-mill buildings at San Quentin prison, has been indefinitely postponed.

The Governor has vetoed the bill requiring the Prison Directors to close down the sash and door factory on the ground that this had already been done by the directors at the Governor's suggestion, and that the power to regulate such matters is inherent in the directors under the Constitution.

The Governor has signed the bill for a State Reform School for juvenile offenders; also establishing an Insane Asylum in Southern California; also creating Orange county; also making an appropriation for a State mineral cabinet; also for an electric plant to utilize the American river at Folsom; also for a fence around the Marshall monument.

In the Senate, the Assembly concurrent resolution asking our Congressmen to take action to secure the granting of the entire watershed of the Yosemite valley to the State, and the election by the Legislature of a board of three salaried commissioners, has been read and placed on file.

A concurrent resolution has been adopted asking the President to open up to settlement large tracts of agricultural land heretofore claimed as desert land and withdrawn from the market by a former Secretary of the Interior.

A long discussion was had on the Senate amendment increasing the appropriation for the State Mining Bureau to $100,000 from $60,000. The amendment was finally concurred in. The bill appropriates $70,000 for the Geological Survey work in the field, and $30,000 for the support of the Bureau. This is $40,000 more than was voted by the last Legislature.

The Diltz Mine.

Capt. John S. Diltz writes us from Mariposa that his mine now looks better than ever and is evidently of greater value. Although he has had but little water to prospect, a glimpse can now be had of what there is in the mountain. It would be impossible to find out the extent of the deposit without water to wash off the surface and expose the under layers of quartz. The whole paying vein-matter is in porphyry and the quartz stringers in the placers run some 200 feet from the hanging-wall. Little quartz has been milled, though the best that has shown free gold has been pounded out in a hand-mortar. The greater bulk of the vein matter lies under the hanging-wall. Capt. Diltz says if he can sell 1250 feet of his patented ground for a fair price he will go to Pittsburg for iron pipe and bring in water to work the ground. Capt. Diltz has very peculiar mining ground, both quartz and placer combined, but he has not had capital to properly work the deposit. He has owned the ground for many years and occasionally comes across some very rich spots. It would cost about $30,000 to bring water from Snow creek to the Diltz and the Whitlock mines, both of which could then be worked extensively.

SCARCITY of water, either in the Carson river or at the disposal of the water company, will cut no figure in curtailing the bullion yield of the Con. California and Virginia mine, as the management will operate the California mill by steam when the water supply falls short. The ore reserves in the mine are ample to keep the California and Morgan mill stamps in full operation for many months.

A NEW chemical laboratory to cost $68,690 will be built at the State University, Berkeley.

Death of Carlton Newman.

It is with sincere regret that we have to record the sudden death of Carlton Newman, president of the San Francisco Glass Works. Mr. Newman was suddenly stricken down when in apparently good health. He was out on business on the evening of Friday, the 7th inst., and returned home slightly indisposed. He rested well that night, but arose in the morning feeling still more unwell. His trouble appeared to be in his respiratory organs, coupled with weakness and irregularity of pulse. These symptoms grew rapidly worse until about 1 o'clock, when he died from failure of action of the heart.

Mr. Newman arrived in San Francisco in 1862. He had already acquired a thorough knowledge of the glass manufacturing business in Pittsburg, and upon his arrival here saw an opportunity to build up that industry in this city. He started on a small scale at the corner of Rich and Townsend streets, but inside of two years his works were totally destroyed by fire, and he was left penniless. But nothing daunted, he immediately went to work with his friends and soon re-established himself again in the same business. From that time to the time of his death he has prospered, and built up a large and important industry, which now ranks among the most flourishing in the city.

In a short time after his second start he effected a consolidation with the Pacific Glass Works. At the time of his death he was sole proprietor of the extensive works under his charge. He was an inventor early in life, and secured the means of reaching this coast by the sale of two inventions. Mr. Newman was born in Wheeling, West Virginia, June 26, 1829. His life since he reached manhood has been one of busy and successful industry, and he largely enjoyed the respect and confidence of all with whom he came in contact. He was a man of warm and general impulse; manly and outspoken in all things. He fulfilled all the precepts of practical religion. Liberal in all things, there was nothing of narrowness about him either in religion, politics or social life. As an evidence of the estimation in which he was held by his employes, we need but refer to the fact that nearly all were present in a body at the last solemn rites over his remains.

Mr. Newman was an active member of the Manufacturers' Association of this city, and had just been elected a Director of the Mechanics' Institute. He was a Royal Arch Mason and member of Occidental Lodge of this city. He was also an Odd Fellow and member of several beneficiary associations. He leaves a widow, one son and three daughters—all of the latter married. He left two half-brothers, one Wm. H. Murray of the *Journal of Commerce* of this city and the other in business in Chicago. He was buried in accordance with the beautiful and impressive rites of the Masonic ritual. Notwithstanding the stormy character of the day, the large hall of the Masonic Temple was crowded by those who sought to do honor to his memory by their presence at the last sad rites which consigned to the earth all that was mortal of Carlton Newman.

LOS ANGELES MINES.—Messrs. Johnson, Dunham & Crow of Los Angeles have bought about 2000 acres of placer mining land, also Richard Kitchline's interests in three quartz leads 12 miles northwest of Newhall. They leave for San Francisco to purchase necessary machinery to reduce the quartz. Late assays and mill tests show very satisfactory results. These gentlemen seem well satisfied with their purchase.—*Los Angeles Times.* [We are informed that this item refers to the "Cora Belle" mining interests. It may be remembered that the "Cora Belle" was "wrecked" by bad management and bickering among the owners a short time ago. Interest has, however, been revived in the region referred to.—EDS. PRESS.]

ELECTRIC-POWER TRANSMISSION. — The Truckee *Republican* is authority for the statement that 18,000 acres of land have been bonded along the Truckee river for the purpose of erecting mammoth electrical works at a point near Bronco, between 17 and 18 miles distant from the Comstock. These electric works are for the purpose of transmitting on copper wires to the Comstock the water-power of the Truckee river to operate stamp-mills and to hoist ore from the mines.

BARNEY PRICE, who died at Virginia, Nev., last week, was a well-known mining man in Nevada. In the early days he was foreman of the Challenge. He was foreman of a mine at Treasure Hill, White Pine, for the California bank; also for U. S. Senator George Hearst at Belmont, Nye county, where he had charge of the Monitor and Canfield mines. At Candelaria he was superintendent of the Northern Belle.

THE STAR MINING AND REDUCTION CO. held a meeting in Helena, M. T., on March 5th, and elected the following trustees: Henry Klein (Pres.), John M. Shopp, (V. P.), Walter N. Granger (Sec'y), Albert Kleinschmidt (Treas.), J. L. Waggoner (Gen'l Manager), and Adolph Hiberlein (Ass't Manager). They commence work in a few days, bringing out concentrates. Messrs. Klein, Kleinschmidt and Shopp leave shortly for the mine.

WM. IRELAN, JR., has been reappointed State Mineralogist of California by Governor Waterman.

[SPECIAL NOTICE.]

Bakersfield and Kern County Attractions.

A Desert Converted Into Fruitful Farms by Irrigation.

[By R. M. E.]

Many eyes are now turned to Kern county, in the extreme southern portion of the San Joaquin valley, the southern part of Central California, where 1,250,000 acres of fertile land await the settler. For years the development of this splendid county has been checked because the parties holding the land would not sell. Now the fiat has gone forth to put the property on the market, and colonists are rushing in to get the lands before they are all purchased. A fine system of irrigating ditches is supplied from Kern, Buena Vista, Tulare and Goose lakes. In addition to these abundant sources of water supply, artesian water is obtained at a depth of 200 feet or upward. The highest mountain in the United States, Mt. Whitney, 15,056 feet, together with other lofty peaks, sheds its melting snows into the Kern valley, but the waters of the Kern river alone are capable of irrigating all the valley, if properly stored and preserved.

Progress.

About fifteen years ago, outside of Bakersfield, the county seat, there were not a dozen families and the valley was considered barren, but this land was waiting for water. The debris of the mountains contains the elements of tree and plant life, and water transforms it like the touch of a fairy's wand. The mountains in that vicinity are composed of friable granite constantly disintegrating, and the river flows over gypsum beds which are worn away and and deposited on the sands. The total value of all county property last year was $8,990,521, or a gain in one year of $2,649,582.

Products.

Alfalfa is the staple crop. The rich fields of this valuable forage plant yield from eight to ten tons per acre annually, besides furnishing some pasturage. Wheat and barley thrive. The products of this county include cotton and sweet potatoes, melons and delicious fruits of which the grapes in our cut on page 249 of this issue are a fair sample. This is a mammoth variety of the Black Hamburg and is taken from a photograph of a vine in Bakersfield, whose immense clusters give but an imperfect idea of the fertility of this region. Corn, planted in rotation with wheat or barley, and as late as July, yields 60 bushels to the acre, but if planted in April, twice that quantity. Here are grown citrus, nut-bearing and deciduous fruits. When six years old the pecan bears in Kern, which is something remarkable, oranges flourish and it is an Eden for flowers, over 200 varieties of the rose alone being grown there. Chestnuts, prunes, quinces, small fruits, pomegranates, apples, pears, apricots, plums, nectarines, walnuts, butternuts, mulberries, figs, persimmons and olives, together with grain and vegetables, afford a variety of foods to the settler, while an abundance of forest trees provide a cheap fuel. Dairying is an important industry and the county is regarded as one of the best for poultry, the products being rapidly disposed of in San Francisco and Los Angeles. The alluvial soil with a sprinkling of alkali is excellent for beets. Mangel-wurzel on the Lakeside ranch stood 2½ feet above ground and averaged one ton in weight to 100.

The Chief Town

Is Bakersfield with five hotels and three churches, six general stores, ten fraternal societies, with an assurance of a Grange of the P. of H., which will make eleven, four dry-goods stores, four variety, two book stores, etc., etc. One hotel, the Southern, will cost $1,000,000; the Masonic temple cost $30,000; water-works and a first-class fire department make this an attractive residence spot. Sumner, connected by a car line with business center, only one-half mile distant, may be reckoned as virtually the same town. Delano, 32 miles west, on the S. P. R. R., and about the same distance from Tulare, has a good future. Other stations and settlements offer special advantages, but we lack the space to describe them. Suffice it to say there are 39 school districts, and the examinations are so rigorous that only about 20 per cent of the teachers can pass and obtain their certificates. In addition to the abovenamed advantages, this county is notably rich in gold and silver, copper, fire-brick clay, limestone, marble, petroleum, building and lithographic stones, and evidences have been found of the existence of iron, coal and quicksilver.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, term of subscription, and give it their own patronage, and as far as practicable aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

AN experimental run of Occidental Con. ore is to be made at the Alta mill to test the double process of concentrating and amalgamating. If a satisfactory result is obtained, the new 20-stamp mill to be erected by the Occidental Company will be similarly equipped.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, March 14, 1889.

The local money market is working to more general ease. The rains of the week, visiting as they did all sections of the State, give assurance at any rate of good grain crops, and with the usual April rains very large crops are an important factor in creating more ease in the money market by inspiring the more timid capitalists with a greater feeling of confidence, which naturally results in their willingness to place money on term loans to the best advantage, rather than keep it idle. After the storms and a general cleaning up, it is claimed by the well-informed that many contemplated improvements and new ventures will be put into force, which will necessarily have a directly favorable bearing on trade and also on all industries. So far there is very little call for money, either for legitimate or speculative purposes, but a more active demand is looked for in the near future.

In grain futures the dealings on Call the past week partook of a timid character, as if operators were feeling their way. The rains and ships are having a decided bearing on the market.

In local securities, trading the past week was quite active, with Spring Valley Water stock apparently the favorite. There is a feeling among the usually well-informed that the inside manipulators of the stock are trying to break it to still lower figures. It is also thought that the Hawaiian Commercial stock is well out on the public, as is that of two or three other incorporated companies' stock.

The value of foreign imports into this port last month was $4,705,166.

The last steamer leaving for China took Mexican dollars valued at $37,120, gold coin $13,713, gold dust $200, and silver bullion $212,000. Of the latter, $95,000 was for Bombay and $117,000 for Shanghai.

For the week ending March 9th there were loaned in this city on realty $275,272. The lowest rate of interest from banks was 6 per cent per annum and the highest 7 per cent.

Quicksilver is slow at the recent decline. Refined borax is reported to be scarce. Pig lead, after advancing to $3.75, fell back to $3.72½, closing easy. Copper is slow. Holders are unwilling to make further concessions. The market appears to be shaping into a better position. Pig tin is without particular change. The demand is said to be improving.

Capt. Curtis and Col. R. F. Morrow returned the past week from a visit to the Comstock. They are both reported to speak very hopefully of the Gold Hill group of mines. The former person was sent as an expert to report on the Confidence and Challenge mines.

SILVER—The market held fairly steady throughout the past week at from 92⅝@93c, the most of the sales being at the latter figure. The market is reported to be quiet, with the stock gradually increasing. As yet, the output of bullion is no larger, but an increase is looked for in the near future. This opinion is grounded on authentic advices of heavy snowstorms in the mountain ranges, and increasing supplies of water for mill motive-power.

QUICKSILVER—The market is slow. Receipts are light, owing to the bad roads.

COPPER—Contrary to expectations, copper has not receded much. It was generally thought that the price would go down below 14c. The controllers and agents of the American mines are reported to be in New York arranging for future operations. Col. Ranlett of this city is now there in the interests of the mines on this coast that he represents.

COAL—The market shows quite a reduction in West Hartley, Scotch splint and Liverpool steam for prompt shipment. The decline is said to be due to the arrival of a large number of American vessels in Liverpool, and their being attracted to this port by reports of good crop prospects. To get cargoes they offer to take in coal at a less rate of freight. It is very generally claimed that the number of vessels on berth to load Australian coal for this port has increased quite largely, but that information on the subject is kept quiet, probably for freight speculative purposes. It is stated that the low prices ruling for coal has induced the coast collieries to reduce their output on an average fully one-third.

IRON—The market continues heavy. Consumers buy in a hand-to-mouth way. They are induced to enter the market by concessions on asking prices. This refers to spot to arrive and also for shipment. The large supply of available tonnage in England has caused lower freights to be quoted from there to this coast. The English iron market is reported very strong, as are the Eastern markets.

LEAD—The market is without change. The demand continues fair.

TIN—On last Friday the market for coke tinplate jumped up to $6 upon a report of a vessel bound for this port, with large invoices, being compelled to put into a port in one of the Falkland islands. This advance was maintained for a short time only, for it was soon made known that another vessel with large consignments is nearly due, while imports by rail from the East can be made for less money. Pig tin has a firmer, stronger tone. The English market is slightly firmer.

Mining Share Market.

In mining stock the Tuscaroras have held up fairly well, as if the manipulators are floating all they can on the basis of present prices. The Bodie and Quijotoa stocks are being depressed and kept at low figures, notwithstanding news from the leading mines in the two districts is of a very favorable character. The impression in certain quarters is that some blocks of the stocks are out which insiders are desirous of securing. In the Comstock stocks the movements of the market warrant the belief that inside manipulators are about ready for a short but active campaign. There does not appear to be any doubt but the late and unwarranted depression brought in large lines of stock which have enabled the inside to concentrate on certain stocks so as to enable them to peddle their "goods" out on the public. In this they will be greatly aided by more water in the Carson river, large deposits of snow on the mountain ranges and in several of the mines, work being about ready for stoping out higher-grade ore. More milling facilities, increased bullion production, more dividends and reports of important ore strikes are important factors in allowing the inside to load up the public with cheap stock at high prices. Private and seemingly reliable advices report an important improvement in the Mexican crosscut on the 1465-foot level, that in both the upraise and winze in Ophir on the 1465-foot level, the ore development is proving more valuable than before claimed. In Union, crosscutting is to be started soon. Con. Virginia is said to be richer in mineral ore than at any time since 1886. In Crown Point they are stoping out ore for milling, which assays from $25 to $45 a ton. This will be milled as soon as they are through with low-grade ore now being milled. In this mine they are getting into rich ore on the 600, 700, and 800 levels. They have trebled the number of miners at work in the mine within the past three weeks. Reports of important work in other mines are afloat, but authentic information is hard to get at this writing. The official reports made at the annual meeting of Hale and Norcross and Potosi are of a very encouraging character to stockholders, particularly holders of the former. They confirm advices heretofore published in these columns.

Con. Virginia carried over a surplus of $90,000 from February into the March account.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

UNION PRESSED BRICK AND TERRA COTTA CO., March 12. Capital stock $200,000. Directors—John H. Wise, H. T. Scott, O. E. Moore, Charles H. Frost, T. H. Downing, S. G. Hilborn and W. C. Price.

MISSION HOME AND LOAN ASSOCIATION. Capital stock $1,000,000. Directors—D. Richards, C. W. Taber, J. H. Dawson, A. B. Maguire, H. H. Mayhew, W. T. Barnes, J. H. Grady, S. H. Brown and G. E. McPherson.

MIDAS G. M. CO., March 13. Location, California. Capital stock, $300,000. Directors—S. T. Lawton, A. Halsey, T. Donohue, G. W. Cox, John A. Thomas.

HILLER DRUG CO., March 13. Object, to manufacture and sell medicines. Capital stock, $500,000. Directors—F. Hiller, Geo. T. Marsh, William Gruenhager, A. B. Kinne and George G. Gould.

SAN FRANCISCO COAL AND BITUMINOUS ROCK CO., March 13. Location, Contra Costa Co. Capital stock, $1,000,000. Directors—J. F. Turner, J. W. Brown, P. B. Nagle, R. S. Sterrett and M. S. Knoll.

THE California miner, Squire, who recently called at the Philadelphia Mint for 104 ounces of gold dust he left there in 1855, has finally obtained his money. The ink on the certificate of deposit had faded, which made some difficulty.

MINING SHAREHOLDERS' DIRECTORY.

COMPILED EVERY THURSDAY FROM ADVERTISEMENTS IN MINING AND SCIENTIFIC PRESS AND OTHER S. F. JOURNALS.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

From the official report of U. S. Patents in DEWEY & CO.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING MARCH 5, 1889.

398,936.—GRINDING PAN—M. P. Boss, S. F.

398,937.—ROTARY HARROW — A. C. Brown, Eugene City, Ogn.

398,942.—SAWMILL SET WORKS—F. W. Cook, S. F.

398,967.—MAIL-BAG FASTENING—Jos. Jacobs, S. F.

399,065.—COIN ADJUSTER—Geo. McLoughlin, Carson, Nev.

399,209.—ELECTRIC AMALGAMATOR—J. H. Rae, S. F.

398,989.—WRENCH—J. Tomlinson, Folsom, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SAWMILL SET WORKS.—Frederick W. Cook, S. F. No. 398,942. Dated March 5, 1889. This is an improvement in those set works by which the knees or standards are properly controlled and adjusted. The invention consists in novel constructions and combinations.

MAIL-BAG FASTENING.—Joseph Jacobs, S. F. No. 398,967. Dated March 5, 1889. The object of this invention is to provide a simple and effective fastening for mail bags which can be rapidly operated and is not liable to get out of order. The tag or destination-card can be readily inserted in place and is held securely by the same operation which completes the main fastening of the bag. The tag is in the most convenient place for reference at all times, whether the bag be full or whether the flap be turned inside the mouth of the bag when ready to receive mail matter.

ORE-GRINDING PAN.—M. P. Boss, S. F. No. 398,936. Dated March 5, 1889. This is a pan for grinding ore in which a muller rotates within the pan and crushes the ore between its shoes and the dies of the pan. The pulp is fed into the center of the muller and is confined therein. It thence passes down and is directed by inclined grooves to and between the shoe and die, and thence, being ground, passes directly out of the pan through an opening in the base of the pan-rim, no plug being used as in ordinary pans. This is the only course open for the pulp. It can pass out in no other way but between the shoe and die, and therefore every bit of it is once subjected to the grinding action, and once only. In many of the ordinary pans the pulp is fed into and fills the pan itself, and some portions may pass between the shoes and dies many times before other portions are subjected to the grinding action at all; but in this pan the shape of the muller so confines and directs the pulp that every bit of it is ground successively in its passage to the discharge.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Savage, March 9, $16,837; Peerless, 9, $7170; Cons. California and Virginia, 9, $96,146; Hale and Norcross (for February), $68,500; Savage (for February), $27,878; Hanauer, 6, $2100, 7 $2200, 8 $2100; Hale and Norcross, 13, $19,361; Navajo, 13, $8000.

SOME of the sulphurets from Nicolia, B. C., have been treated in San Francisco, and averaged $150 per ton. Some rich ore is now coming out of the Tubal Cain mine of the Nicolia Mining Co.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

A. F. JEWETT—Tulare Co.
F. B. LOGAN—Southern California.
H. G. PARSONS—Southern California.
GEO WILSON—Sacramento Co.
J. C. HOAG—San Francisco.
CHAS. F. BLACKBURN—Idaho.
FRANK S. CHAPIN—Colusa Co.
MRS. C. J. STEPHENS—Sierra Co.
R. G. HUSTON—Montana.
E. H. SCHAEFFLE—Calaveras and Tuolumne Cos.

THE artesian well being sunk in San Luis valley, below Alamosa, Col., will turn out to be a mine rather than a well. Gold was found by the drill at 40 feet, and, after getting through some hard volcanic rock, at a depth of 70 feet, rich silver ore has been found.

The Mechanics' Institute.

At the annual meeting of the Mechanics' Institute it was reported that the gain was 400; the increase in fees and dues $2302.50, and the outside circulation 100,500 volumes. During the year, also, 1112 subscribers have joined, and 13 life members, making a total of 1125; withdrawn and dropped, 728; gain, 397; and in good standing at the present time, 3557. There have been received and entered in the accessions catalogue 3713 bound volumes, also 887 unbound volumes and pamphlets, making a total of 4600. The number of volumes at last report was 45,051; this year the number is 47,656.

The report of Treasurer J. A. Bauer was equally satisfactory. The following is a synopsis of his report: Receipts—March 1, 1888, to February 28, 1889, $32,556.04; disbursements—same time, $30,872.58; balance, $1,683 46.

Pavilion fund—Receipts, $40.134 50; disbursements, $34,813 71; balance, $5320 79.

Sinking fund—Receipts, $3981.02; disbursements, $3556.51; balance, $424.51.

Folsom-street lot—Receipts, $7444.33; disbursements, $7444.33.

The assets of the Institute consist of land fronting on Hayes and Larkin streets, which, with the improvements, is not worth less than $1,000,000; Post-street lot and library building, $175,000; Sixteenth-street property, $125,000; books, furniture, etc., $80 000; cash in treasury, $7558.66; total, $1,387,558.66. Against this there is a mortgage indebtedness to the Hibernia bank of $120,000; to the State University, $45,000; leaving a net balance of $1,212,558 66.

A communication was received from the president, P. B. Cornwall, tendering his resignation, on account of pressing business affairs needing his close attention. On motion of Wilson, seconded by A. S. Hallidie, a resolution was adopted expressing sincere regret at the resignation of Mr. Cornwall, the resolution being ordered spread upon the minutes.

A. S. Hallidie then moved that a committee of three be appointed to draft a suitable resolution on the death of Carlton Newman. The following gentlemen were appointed: A. S. Hallidie, George Spaulding and I. C. Stump.

At a meeting of the Trustees held later, the following officers were appointed: David Kerr, President; J. C. Stump, Vice-President; J. A. Bauer, Treasurer; A. W. Starbird, Secretary; and S. J. Hendy, Corresponding Secretary. George S. Ames was also elected to the position of Trustee, rendered vacant by the resignation of P. B. Cornwall.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or of some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

For New Subscribers—Something New and Rare.

PACIFIC COAST RELIEF CHART.

PHOTO-FACSIMILE.

With subscription paid one year in advance for this paper, and 10 cents to pay postage and mailing tube, we will send a fine Photoplate Relief Chart of the Pacific Coast, embracing California, Nevada, Oregon, Washington Territory, and part of Montana, Idaho and Utah, Photographed from a topograph'cal relief model in plaster (5 feet 3 inches by 5 feet 6 inches in size), made recently by Isaac Winston and Prof. Geo. Davidson (the latter Chief of the U. S. Coast Survey on this Coast for the past 20 years),

While it does not take the place of an ordinary map, it illustrates, comparatively, the elevations and depressions of the principal mountains, valleys, rivers, lakes, ocean and bay-shores of the Pacific States and Territories, and makes a permanently useful, handsome and desirable picture for either library, office or home.

The charts are 19x24 inches, well suited for framing, if desired. It is as handsome, and even more durable, than an ordinary photograph. Seldom is so choice an article offered as a newspaper premium. Sent to old subscribers on the same terms on paying one year in advance of current date. Subscribe and secure this permanently valuable chart.

Address Publishers of this paper, No. 220 Market St., S. F.

Portland, Or. Sydney, N. S. W.

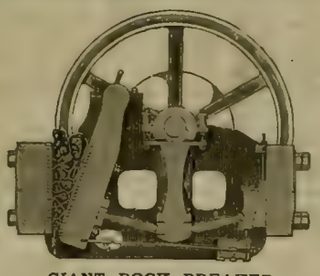
PARKE & LACY,

21 and 23 Fremont Street, SAN FRANCISCO, CAL.

—IMPORTERS AND MANUFACTURERS OF—

MACHINERY

ENGINES, BOILERS, STEAM PUMPS.



ROCK BREAKERS, PULVERIZERS, CONCENTRATORS.

GIANT ROCK BREAKER.

Westinghouse "Standard" and "Junior" Engines, Rock Drills and Air Compressors. Saw and Planing Mill Machinery, Machine Tools, Governors, Injectors, Oil Cups, and Lubricators.

BELTING, OILS and GENERAL SUPPLIES.

We are prepared to give estimates for Hoisting Works and Pumping Plants, Stamp Mills, mSelters and Concentrators.

ARE YOU GOING TO PUT UP MACHINERY OF ANY KIND?

Are you going to make any change in machinery? Are you freighting by team or packing on mules? Do you want Pulleys on Shafting already up? If so, don't fail to look into the merits of THE DODGE PATENT INDEPENDENCE

WOOD SEPARABLE or SPLIT PULLEYS.

They are the Lightest, Strongest, Best Balanced and most Convenient Pulleys made in the world.

Adapted to any power required. Time, trouble and money saved by using these Pulleys.

☞Price List and Catalogues mailed free.

Also SIMONDS' SAWS furnished to order as follows: Inserted Point (Mill and Edger), Inserted Tooth, (California Pattern,) Solid, Shingle and BAND SAWS, all sizes, Crescent Ground Cross-Cut, etc. Also Planer Knives.

SIMONDS SAW CO., 513 Mission St., San Francisco.

The EXPLORERS' and ASSAYERS' COMPANION.

A Third Edition of selected portions of the "Explorers', Miners', and Metallurgists' Companion."

A practical exposition of the various departments of Geology, Exploration, Mining, Engineering, Assaying, and Metallurgy.

Price, $6.00 post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

BY J. S. PHILLIPS, M. E.

The work is divided into four parts—Rocks, Veins, Testing and Assaying. The geological chapters are intended to give miners a practical idea of the various formations. The chapters on mineral veins are derived from long observation, and the section on exploration has been carefully considered. All that relates to discrimination and assay of minerals has been kept as free from formulæ as possible. The work is written for practical men, and all the explanations and descriptions are clear and to the point. It is so prepared that it is useful to uneducated men as well as scientists.

HORACE D. RANLETT,

Ores, Mining, and Commission,

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes) $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

Mining and Scientific Press.

THE BEST PRACTICAL MINING JOURNAL IN THE WORLD.

Established in 1860, this paper has been eminently successful as a popular and useful mining and mechanical journal. Relative to precious metals especially, it is the leading mining paper of the world.

Subscription, $3 a year. Advertising rates, moderate. Send for samples and further information.

It is largely patronized by the leading Miners, Mine Owners, Superintendents, Engineers, Metallurgists, Chemists, Manufacturers, Mechanics, Scientific, Professional and Industrial "Men of Progress" on the Pacific Coast and many leading Mining Men throughout the mining fields of the world.

It is by far the best advertising medium in the Pacific States and Territories for Mining, Mechanical, Engineering, Building and Manufacturing Tools and Implements, Goods, Supplies, etc.

Being thoroughly able and reliable in its editorial and business management, and long established in the most progressive industrial portion of the Union, at present its power as an advertising medium is unsurpassed.

New York Office, 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

AGENTS FOR THE PACIFIC COAST OF

BRYAN'S ROLLER QUARTZ MILL,

The most perfect Roller Mill made, for the following reasons:

1. It is cheaper.
2. It is more durable.
3. It crushes a larger amount of ore with less power.
4. It amalgamates a larger percentage of the gold.
5. Its "clean-up" is quicker and fuller.
6. It is portable, requires no frame-work, and is ready for the foundation as it leaves the shop.

Full Descriptive Circulars of any of the above sent on application.

OFFICE OF THE CANDELARIA CONSOLIDATED MEXICAN MINING CO., SAN DIMAS, DURANGO, MEXICO, October 25, 1888.

Risdon Iron Works, San Francisco—GENTLEMEN: Our Company has been operating three of the 4-foot Bryan Roller Quartz Mills, one of which has been running steadily for three years, one for two and one for one year. Our quartz is very hard; we crush through a No. 60-mesh screen. Our mills run 55 revolutions per minute, and each crush through 60-mesh screen 12 tons in twenty-four hours; through 50-mesh, 15 tons; and through 40-mesh, 18 tons. This proportion has been continuous. One set of Dies will crush from 1500 to 1600 tons. One set of Tyres will crush 1500 tons. One ring plate will crush from 2200 to 2300. The mills require very little attention. At our mill an ordinary "peon" earning one dollar per day has complete charge. In regard to sliming, in comparison with stamps by reason of the discharge surface and the continuous agitation by the scrapers, a MUCH less amount of slimes is created. A three years' experience teaches me that, in every respect, the mills are a complete success and of material benefit to the mining world. They can be set up and running in 48 hours, and can be dismounted in the same time and removed to wherever desired. Ours were packed on our mule trail over as difficult a road as any in Mexico. As a gold amalgamator, it is unequaled by any mill now in existence.

Yours truly, D. M. BURNS, Superintendent.

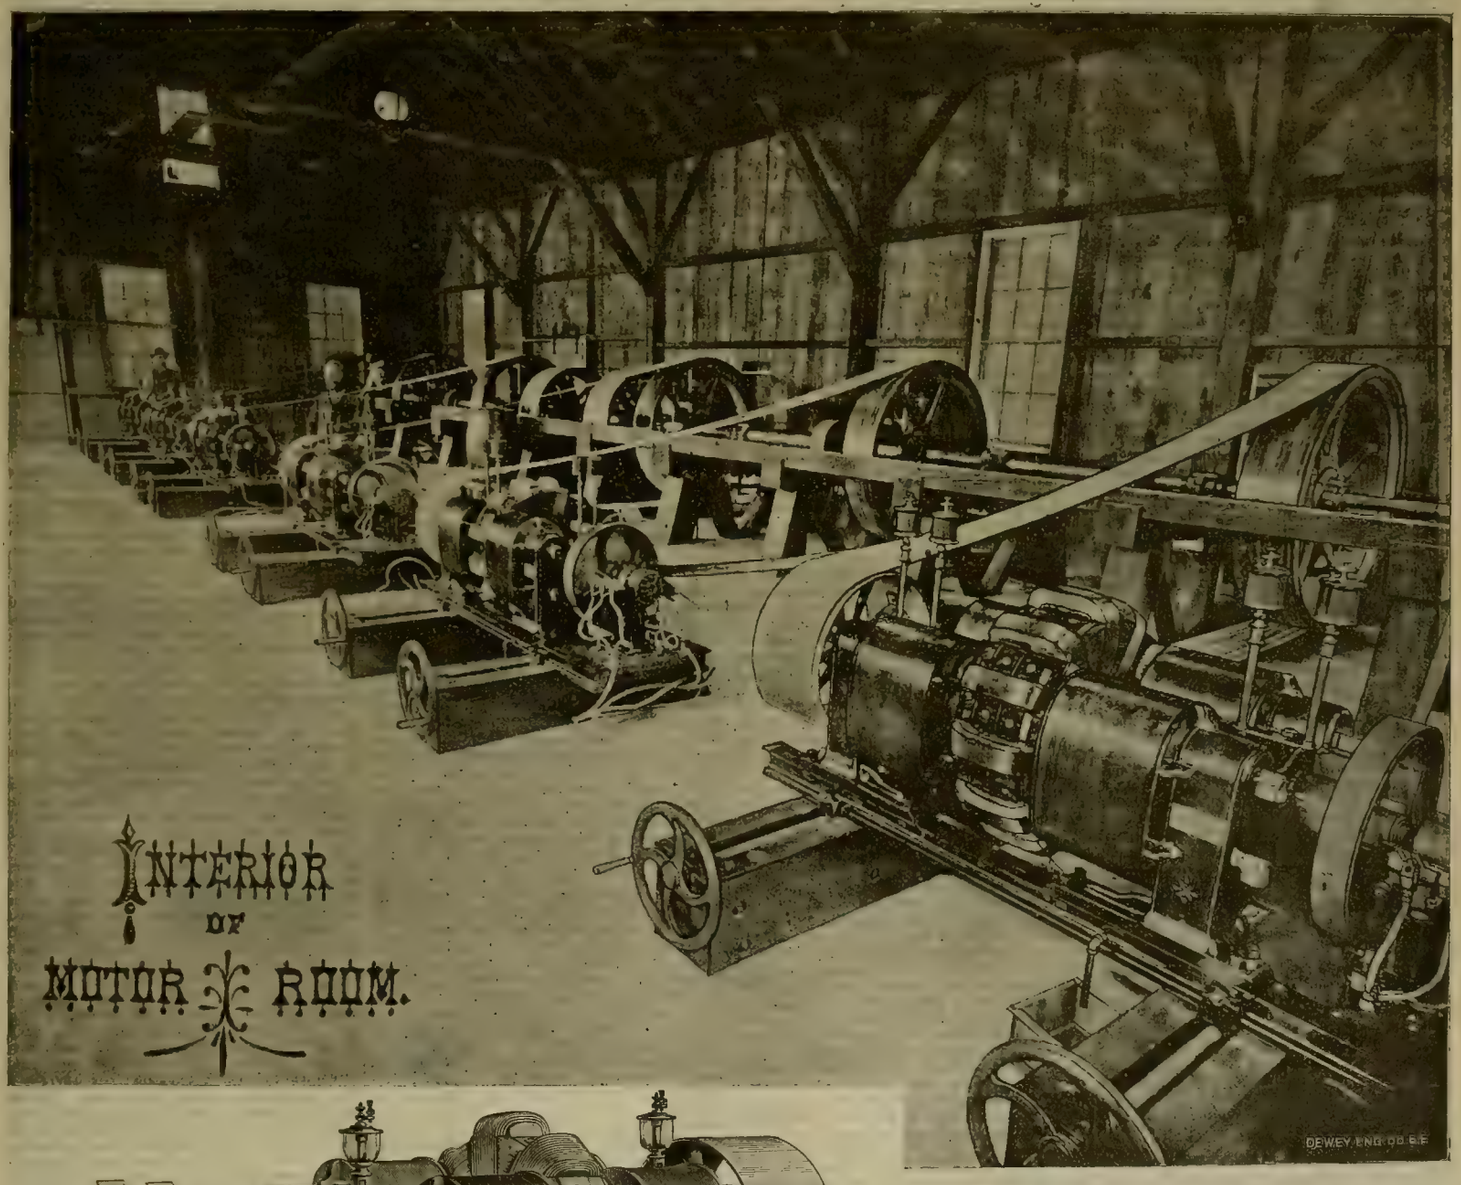
MINING AND SCIENTIFIC PRESS.

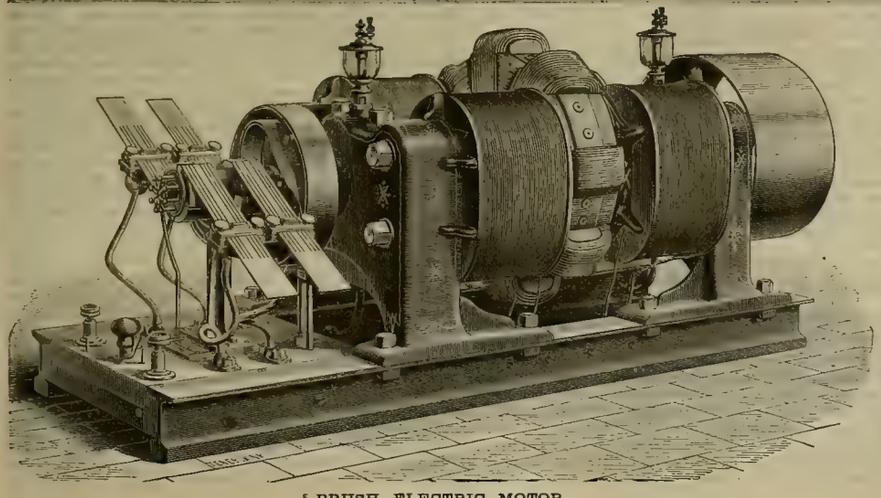
An Illustrated Journal of Mining, Popular Science and General News.

ELECTRIC-POWER EDITION—TWENTY PAGES.

BY DEWEY & CO. Publishers. SAN FRANCISCO, SATURDAY, MARCH 23, 1889. VOLUME LVIII. Number 12.



INTERIOR OF MOTOR ROOM.



BRUSH ELECTRIC MOTOR.

Electric-Power for Mining Work.

We have on numerous occasions within the past two years called the attention of the mining community to the great advantage of electric-power for running mills, pumps, hoists, and all machinery at mill and mine, under proper conditions. In this number of the PRESS we give a detailed description, with engravings, of the great electric plant on the Comstock, which is now doing satisfactory work. This marks a very important step in the progress of both mining and electricity, and before long we may expect to see many other electric plants connected with mining works.

Within any reasonable distance the electricians can convey the power to be utilized in any desirable way. The loss of power increases with the distance, but for 12 to 15 miles the system is entirely practicable. With progress in this branch of science no doubt much larger distances will become possible; in fact, they are so now under conditions of perfect insulation against high electro-motive force.

There are hundreds of places on this coast where water-power can

(*Continued on page 208.*)

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

Mines of Angels, Calaveras County.

EDITORS PRESS:—The mines of Angels embrace those of Robinson's Ferry, Carson Hill, Albany Flat and Altaville, located on the different branches of the mother lode, and are but a few miles distant, all drawing their supplies from Angels. Their claim for recognition is not of a late day, nor are the mines a recent discovery, but rather the result of present development on well-known quartz veins. Prof. Whitney, in writing of this section, states: "The breadth of the belt of metamorphic rocks which inclose the gold-bearing quartz veins is 24 miles in Calaveras county. Starting from the west, or at the bottom of the Sierra, the first rock encountered is horizontally stratified and undisturbed tertiary sandstone. To this succeeds the belt of Mesozoic metamorphics in nearly vertical strata. The lower edge is composed of talcose and chloritic slates, weathering irregularly. Next comes a wide belt of dark-grayish green, somewhat porphyritic material which shows a sheeted structure known as 'porphyritic green slate.' This belt incloses another of argillaceous slate, with which is associated the 'mother lode,' or the 'great quartz vein.'"

The most remarkable primary metalliferous deposit of California is the mother lode referred to. Many of the great mines of the State are upon it. It extends from a point a few miles southeast of Merced river, in Mariposa county, through Tuolumne and Calaveras, to near the center of Amador, a distance of 80 miles. This powerful lode is made up of irregular parallel plates of white compact quartz and crystalline dolomite or magnesite, more or less mixed with green talc, and these plates, which somewhat resemble the "combs" of ordinary lodes, are either in contact or separated from each other by intercalated layers of talcose slate. The quartz is chiefly developed in the central portion of the vein and from its color and resistance to decomposition, it gives rise to a very conspicuous outcrop forming the crest of the hills, so that it can be readily seen for a distance of several miles. The mother lode divides into three branches in Calaveras county. At the intersection of the east and middle branch on Carson Hill, $2 800,000 was extracted by the Morgan Mining Co. Here, at the outcrop, the famous and unequaled nugget of 195 pounds, troy weight, of $43,534 value, exceeding the renowned Welcome nugget of Australia by $2000, was discovered. Numerous nuggets, weighing from 5 to 26 pounds, were found in this same vicinity.

Among companies at present in operation on the different branches of the mother lode is the Calaveras Con. G. M. Co., Limited. This property extends from the Stanislaus river at Robinson's Ferry to Albany Flat, a distance of 1½ miles. At present they are confining themselves to development and have driven a tunnel 543 feet long, crosscutting the mother lode at a depth of 200 feet and disclosing a vein 70 feet in width running from $6 to $8 to the ton. The working force consists of 25 men. Another season will see the mines equipped with a mill of 60 to 100 stamps. Parallel with this company's mines is the famous Morgan mine, now in litigation between Messrs. Fair and Irvin, which, with its neighbor, the Melones, are idle. Joining the Calaveras C. G. M. Co.'s properties on the northeast is the McCreight mine, now the property of Messrs. Hayward, Hobart & Hardy. The vein here shows an average width of five feet, the rock milling from $5 to $200 a ton. The mine is operated by a shaft now 300 feet deep, nine men supplying the 10-stamp mill with quartz. Further on is the Mattison mine of Tullock & Lanes, which is being prospected by a tunnel now in 210 feet and cutting the 30-foot ledge 100 feet deep. Six men keep the 5-stamp-mill pounding away merrily on ore running from $1.50 to $8 a ton.

Adjoining is the Gold Cliff mine, the property of Chas. J. Nickerson and Nathan Niels, which is opened by a cut 275 feet long, cutting the vein 160 feet deep and showing a vein 30 feet in width, averaging $4 to the ton. The mill is of 20 stamps. Following this mine, on the central lode, is the property of the Suffolk G. M. Co., Chas. D. Smythe, superintendent. The 110-foot shaft shows a four-foot vein averaging $5 a ton by free-milling process, but by a recent process of Mr. Smythe's going $60 to $80 to the ton. In consequence the five-stamp mill is hung up until Mr. S. can get his process in operation. Ten men are employed. Parallel with the Suffolk, on the southwest, is the Evening Star mine, the property of Mr. J. T. Curtis, where a tunnel 80 feet long will strike the 10-foot vein at a depth of 100 feet. This property is in the prospecting stage. Adjoining it is the Osborne, a 10-foot ledge with an average of $10 per ton. A tunnel cuts the vein 58 feet deep. Four men keep the Kendall rocker-mill busy crushing its 10 tons in 24 hours. All this property requires is capital.

In the town of Angels, on the east branch of the mother lode, is the Nevills mine, with a "west ledge" 20 feet in width and the "east ledge" 15 feet, developed by a 400-foot shaft. The reported average value of the rock is $7 a ton. The mine has a fine mill of 20 stamps and employs 30 men. Adjoining is the Utica, the property of Messrs. Hayward, Hobart & Lane. Mr. Hayward has brought his knowledge of the mother lode—acquired in operating the Plymouth Con. at Plymouth, Amador county—to bear on this property, and with their resources, have shown just how to work the large bodies of low-grade ore of this great lode to the greatest profit. Their first work was the sinking of three shafts of 370 and 435 feet, to prove the size and value of the ore bodies. This showed up a vein of an average width of 18 feet. As the vein carried a large amount of low-grade ore, reducing the average to $4 a ton, a mill of 60 stamps with 24 Frue concentrators was next erected. The mill is automatic in its operation, and is not excelled in any detail or requisite for the rapid, economical and successful working of the ores, by the famous mills of Dakota. To further reduce the cost of milling, a ditch four miles long was constructed, and from its terminus a stretch of pipe 1½ miles long was laid. This power will soon be applied by Pelton wheels, and thus by displacing the steam-power and attending expense, the cost of mining and milling, now about $2.25 a ton, will be still further reduced. Thus far, the work has been largely of a developing character; now, however, the mine is in shape to work, and the Utica will be heard from as a steady bullion-producer. The working force at this mine is about 80 men.

Adjoining the Utica are the mines of the Angels Quartz Mining Company, owned and operated by J. V. Coleman. The properties were formerly known as the Potter and Doc Hill mines. The mines are opened by two shafts of 200 feet depth each, one of 300 feet and the old Potter shaft 600 feet deep. The latter is now being cleaned out and will be put into shape for working. Mr. G. H. Fox, the superintendent, has been carrying on an extensive system of development which will be still further extended. It was originally supposed that the two veins on these properties were distinct, but development would indicate that they were one, the smaller vein being a spur of the larger. The intervening space is mineralized as well as the vein matter, and the coming summer will see a mill erected of sufficient capacity to handle the 200 feet in width of vein matter to a good profit, as all of the ore is of a fair grade. At present, the ores extracted in prospecting are crushed in the company's mill by three Low cannon-ball mills of a combined capacity of 30 tons in 24 hours. The company has its own construction and repair shops, and everything in and about the works gives evidence of a practical man in charge. The present working force is 30 men.

The ores of this section carry a large amount of sulphurets which are treated by the Angels Chlorination Works of Messrs. Hayward & Hobart, at a charge of $20 a ton. The works have a capacity of four tons in 24 hours, are complete in every detail, and leave nothing more to be desired for the successful working of the ores of this section. Many who resided in Angels five years ago, claim that Angels is at its zenith, but an inspection of the mines operating will show that at the present time the work being done is almost entirely of a developing character, and it is only necessary to recollect that the mines on the three branches of the mother lode extend over a stretch of country 6 miles in length by 1½ in width, which would give an aggregate length of 18 miles of veins, running from 2 to 200 feet in width. That Angels is but awakening and her ore reserves unequaled in extent by any mining town in the State is a mere matter of computation. Angels is distant from the terminus of the S. & C. R. R. and V. S. R. R. 30 miles, communication being by daily stage. The population of the town is now about 1000. The Angels hotel offers every accommodation to travelers. Numerous stores carrying extensive stocks of goods supply the wants of the people. Many fine residences grace the streets, prominent among which is the mansion of Messrs. Hayward, Hobart & Lane, so ably and affably presided over by Mrs. Lane. In the adjoining town of Altaville Mr. D. D. Demorest's foundry, machine-shops and agricultural implement warehouses are an appreciated convenience in operating the mines of this section.

The Union Water Co.'s system of ditches surround the section, furnishing water for milling at 8 cents an inch. Mining timbers sell for 18 cents a running foot; lumber $20 per M.; while miners' wages are $2 50 a day.

The *Mountain Echo* and *County Record* are both published in Angels, and unite to spread the fame of the camp. To the *Echo* is reserved the honor of being the pioneer in the field, and to it belongs the credit of first attracting capital to the mines of this section. The papers should receive the praise and support of every Angelite.

The mildness of the climate makes it possible to operate the mines every day in the year. Good schools, churches, stores, homes and intelligent society make mining life in Angels exceptionally pleasant, and leave nothing to be desired. E. H. SCHAEFFLE.

Angels, March 14, 1889.

Saving Gold and Sulphurets.

Milling Ores on the Mariposa Grant.

EDITORS PRESS:—It was in the fall of 1863 I applied through your Patent Department for a patent copper pan and boiler amalgamator, together with a method of treating sulphurets with salt and extracting the gold. My copper pan was from 4 to 6 feet in diameter, bottom one-fourth inch thick and galvanized with quicksilver. This was set in a furnace. The sulphureted pulp, after being treated to a salt bath and exposed to the air, was sprinkled with mercury and frequently turned over. It was then put into the pan and covered with many times its bulk in salt water and brought to a boil while being stirred with a muller. Mercury will not evaporate at a heat of 212° if well covered with water. The salt causes the whole charge to turn as black as ink and the gold is freed from its coating and settles and sticks to the bottom. After boiling slowly for one hour the pan is filled with clear water. It is then drawn off into a concentrator or run over a burlap incline table, which will save a portion which is not yet decomposed. That which is decomposed flows away in coloring matter, and that which is left on the table is again thrown into the salt-vat and an arastra or a grinding-pan is kept constantly at work grinding on more sands and sulphurets to be placed under the salt treatment in the vats.

While T. W. Park managed the Fremont mines, I worked at the Mt. Ophir mill. I was arastra-man, attending to four large arastras charged with blanket sand. At that time I made what I named a gravity concentrator. It was simply a box or a small barrel set below the mill. The flow of water and sands from the mill was conveyed to the bottom, where it discharged. The light and worthless matter flowed over the top and all the best was left in the bottom. By placing two of those side by side, the flow from the mill could be shifted from one while the other was being cleaned out.

When the Pine Tree and Josephine mines were being worked and the Benton mills on the Merced river were in full blast, I went below the mills and got a panful of the tailings, and took home and panned it down to the clear sulphurets, which I put through my salt treatment. The result was 33 cents per pound. I afterward went there and got some of their tailings, and had nearly the same results. The millmen were jealous, and did not like to have it said that they lost gold. The short of it is: The Josephine and Pine Tree ores are of the most rebellious character, and they did not want to see me make my apparatus pay. In the summer of 1867 that Brummagem was working the Princeton mine and mill, I asked him what chance he would give me in the sands of his tailings, and I proposed to give him $1 a ton more on their quartz if they would give me all the tailings. I set my two gravity machines, and while they milled 300 tons, I concentrated and piled in one heap 45 tons, which was still a large percentage quartz. In the meantime I separated 1000 pounds of sulphurets from the same, and I set up my pan amalgamator.

The 1000 pounds I put under the salt treatment and amalgamated in the copper pan yielded $275, or, say $550 per ton for the sulphurets. The quartz sands separated and ground in arastra paid $30 per ton. Now come my figures for their milling 300 tons, which they said paid $10 per ton, or $3000. Next come my figures for my 45 tons of concentrated sands, $30 per ton for the quartz, $1350; and for the 1000 pounds of sulphurets, $275. This altogether made $1625. I sent a man up to the Hite mine to put up two arastras and vats and boiler for my salt treatment of sulphurets, and I went there and staid several days and instructed him where he could concentrate their sands before they got into the river. As soon as they found out he was making something they bought him out and got him away, and the tailings got away. On the whole I am of the candid opinion that one-third of the gold from the Hite mine was lost; nearly one-half from the Princeton, and two-thirds from the Pine Tree and Josephine.

Mariposa, March 11th. JOHN S. DILTZ.

HALE AND NORCROSS MINE.—At the annual meeting of the Hale and Norcross M. Co., the old directors were re-elected, consisting of H. M. Levy, A. K. P. Harmon, C. P. Eagan, Jos. Marks, M. Hoeflich, C. S. Wheeler, and E. B. Holmes. At a subsequent meeting H. M. Levy was appointed president, A. K. P. Harmon, vice-president; A. B. Thompson, secretary; R. P. Keating, superintendent; and Nevada bank, treasurer. The secretary's financial report shows that the bullion receipts during the year were valued by assay at $986,311.75, and that $224,000 was disbursed in dividends. There was a cash balance on hand March 1st of $12,447.62, with further shipments of bullion to arrive. Superintendent Keating's annual report shows that there are large reserves of ore in the mine between the 500 and 1300 levels, and concludes as follows: During the past year we hoisted 46,525 tons of ore and 31,091 tons of waste rock. The gross bullion yield of all the ore worked during the year was $997,669 93. Besides the extraction of the ore above mentioned, 4441 feet of drifts have been run.

AN ELECTRIC SHOCK.—A lady who with others descended the Chollar shaft on the Comstock to see the dynamos at work, touched a small temporary wire which supplied the current to one of the incandescent lamps, and received a very severe shock. The shock, though not dangerous, threw her down into the giraffe, and her screams brought others of the party to the rescue. Her hands were found to be badly burned and her nervous system received a severe shock.

THE Viola French Copper Co. in Beaver county, Utah, has been attached by the miners for wages due.

Quicksilver Here and Abroad.

J. B. Randol, manager of the New Almaden mine, has contributed an interesting article on quicksilver in California and Europe to the *Engineering and Mining Journal* of New York. Mr. Randol evidently takes a deep interest in this subject, and follows up all lines of information with the closest attention. He makes the point that no new discoveries are being made in California, while mines heretofore worked are becoming exhausted, and this too in the face of improved prices. The further point is made that the foreign production of this article is double that of the home product, that the largest two foreign mines are worked by the Government at lower prices than it is possible to duplicate in this country; that one of these mines has reserves that will last at the present rate of production 70 years and the other has reserves that will last 100 years, while the American mines never have reserves for only a few months ahead, and are obliged to spend large sums of money in unwearied prospecting, often with the most barren results.

The product of the New Almaden mine in 1888 was 18,000 flasks, or 2000 flasks less than in 1887. This mine still retains the lead, producing last year 54 per cent of the total American product. Napa Consolidated was the next largest producer last year, its total being 4065 flasks, a gain of 1185 flasks. The Bradford is one of the latest claims that shows the greatest promise. It only began producing in 1887, when its yield was 1543 flasks, while last year it produced 3848 flasks, a gain of 2305 flasks, or 150 per cent. This mine now occupies third rank, but bids fair in 1889 to take second place. It is in Lake county. The ore thus far taken out has been near the surface, and of course has paid well. Not so with some other mines with deeper workings, which have only been kept open by assessments on stockholders. A notable example of this kind is the Great Western, also in Lake county, which produced 6442 flasks in 1880, and paid dividends, while last year the yield was only 625 flasks, and an assessment was necessary to defray expenses. The Sulphur Bank produced 11,152 flasks in 1881, and only 890 flasks in 1884, followed by assessments. It has since done better, and was last year credited with 2164 flasks.

The yield for the Ætna has fallen off from 3478 flasks in 1886 to 959 in 1888. Some years ago the most noted mines in this State were the Guadalupe and Redington. Each of these was considered a fortune to the owners. The Redington did not pay a large amount in dividends. Both properties are now in the sere and yellow leaf. The Guadalupe has been dropped altogether since 1885, when it returned only 35 flasks. The Redington appears to be fast falling in its wake, the yield last year being only 121 flasks. Mr. Randol shows that the product for the five years ending December 31, 1883, was 293,918 flasks, valued at $8,545,000, or an average of $29 07 per flask. For the past five years the yield was 132,941 flasks, valued at $5,845,000, an average of $36 61 per flask. It is quite evident from this exhibit that if there were much profit in the business, the higher average prices for the past five years would have resulted in an increased product instead of the large decreased yield, which the figures show. That certainly is a logical conclusion, whatever may be its inspiration.

In the face of these facts the Ways and Means Committee in Congress last year had the hardihood to recommend the repeal of the 10 per cent ad valorem duty on this article and place it on the free list. The committee may have thought that a protection of 10 per cent ad valorem was practically no protection, and so remanded the article to the free list. At the average price of quicksilver in this country last year the duty was about 5½ cents per pound. Fortunately the House Tariff bill of Mills & Co. was defeated in the Senate, and so this blow at a specific California industry of much moment has been averted. There was not a shadow of an excuse for the removal of this tax. Though thus far the product is confined to California, and is limited, there is still a surplus for export. The Senate proposed as an amendment a specific duty of six cents in lieu of an ad valorem duty of 10 per cent. But as the Senate amendments to the House bill were not ratified, the whole tariff legislation of the last Congress, about which so many speeches were made in that body and in the late presidential canvass, and about which so many business men had so much worry and anxiety, has gone by the board. California quicksilver-producers hope the next Congress will either let them entirely alone or put a specific tax of 10 cents per pound upon the article in the place of 10 per cent ad valorem tax.

The product of the European mines for 1888 is not at hand, but for the previous five years it was as follows:

	Almaden, Spain.	Idria, Austria.	Italian mines.
1883, flasks	46,143	13,152	6,065
1884	43,099	13,967	7,850
1885	46,739	13,503	6,965
1886	51,199	14,496	7,375
1887	53,276	14,676	7,500
Total	240,456	69,794	35,755
Annual average	48,090	13,960	7,150

The movement to and from England for the past two years was as follows:

	1887.	1888.
Imports, flasks	61,114	73,768
Exports	62,606	47,133

The exports from England last year embraced 10,267 flasks to China, 334 flasks to

Japan, 1744 flasks to Australia and New Zealand, 3076 flasks to the East Indies, 9967 flasks to Mexico, 5038 flasks to Central and South America and Brazil, and 4652 flasks to the United States and Canada. Most of this trade legitimately belongs to California, and would come here but for the fact that Spain and Austria, with their cheap labor and richer deposits, can undersell us. With the duty at 10 cents per pound, and a guarantee that it would be kept there for ten years, capital might be induced to make a vigorous search for deposits of quicksilver in California, and possibly such search might be rewarded with discoveries that would place the industry on a better footing than ever.

MINING PREMIUMS AT THE STATE FAIR.—While the State Agricultural Society has been liberal in the matter of racing purses and agricultural premiums, the mining communities have felt that their special industry has been neglected, and no encouragement has been given to make displays of valuable ores, minerals, etc., which have done so much to enhance the wealth and prosperity of the State, and which will continue to engage large investments of capital and employ a considerable percentage of intelligent and well-paid labor. In consequence of this oversight or neglect the mining counties have not manifested that interest in the State Fairs that they otherwise might, and have found more of value to them in the annual expositions of the Mechanics' Institute at San Francisco than at the exhibits at the State capital. The subject has been called to the attention of the present officers of the State Agricultural Society, and they have expressed a willingness to make recognition of the mineral interests of the State, and will, in their premium list for the next annual fair, offer premiums and medals for displays of gold, silver and copper ores, and other minerals and woods. If these premiums are on a liberal scale, there is no reason to doubt that the mineral display will be one of the most valuable and attractive features of the fair, and with the agricultural, horticultural and vinous exhibits will form a grand combination that will most favorably impress not only Californians but visitors from distant States who may attend.—*Grass Valley Union.*

WATER-JACKET FURNACE. — A Williams water-jacket furnace was brought in on yesterday's train and was visited by many of our local mining men. This is a new patent, designed by J. J. Williams, superintendent of Copper basin, who will erect it at that point. It weighs in the neighborhood of 5000 pounds and costs about $1000; has a capacity of five tons of lead or copper ore every ten hours. Jack Boyd, an old machinist and one fully conversant with this class of machinery, says it is the most complete arrangement of its cost and capacity he ever saw. It is designed to work copper and lead ores, and its completeness, cheapness and its comparative lightness will enable owners of copper and lead properties in isolated districts to procure them, do their own smelting and ship their matte and bullion out on the backs of pack animals. Owners of copper and lead properties, and there are many of them in this vicinity, are anxiously awaiting the first run of this late invention, and if it proves to be the success it promises to be, orders will immediately be forwarded for more of the same make.—*Prescott Courier.*

THE Truckee *Republican* says: It begins to look as though there would be but little railroad wood cut in this vicinity this year. The railroad company has not made any contracts, only one of importance being with the Boca Mill Co. In this case the latter company has been attempting to sublet their contract, but have failed to find any one to take a contract to cut any wood. At the present price of railroad wood contractors find it impossible to furnish wood unless they can secure the very best class of laborers, who will work faithfully for the interest of their employers, and these cannot be secured except at the very highest wages. The railroad company claim that they cannot pay a higher price for wood without increasing its cost for fuel above that of coal. The wood industry was one of the most important in this vicinity, but unless something occurs so that the price of wood will be advanced, the industry will become dormant.

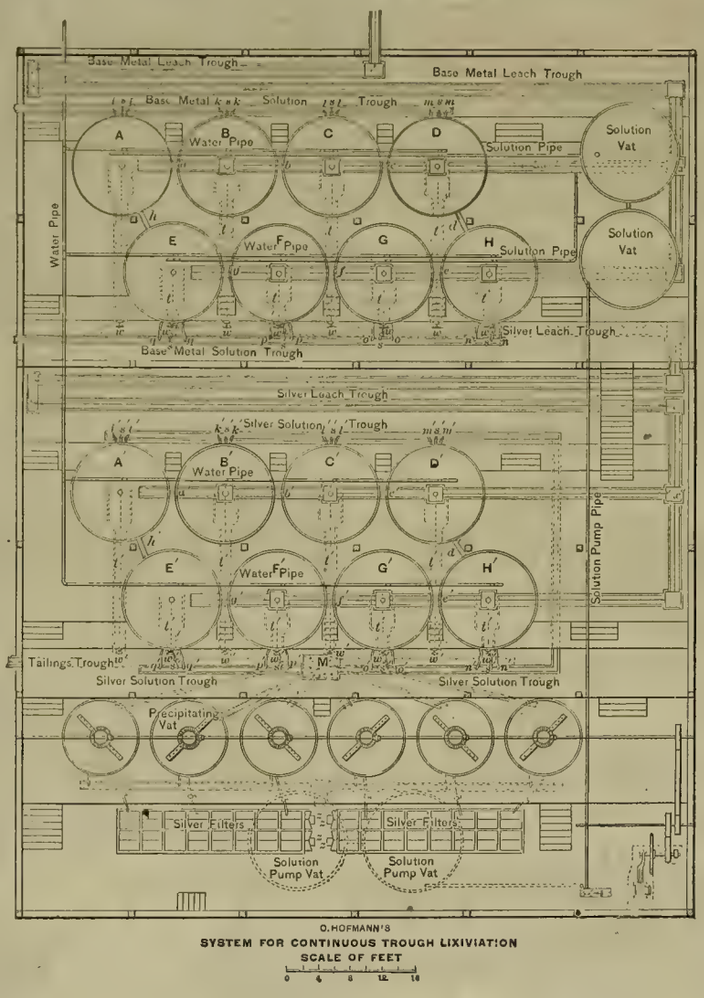
GEN. MILES, U. S. A., has ordered an examination of the harbors of San Francisco, San Diego, San Pedro and Santa Barbara. The examination will be made by artillerists, under command of Major W. L. Haskin, U. S. A. There are already charts of these harbors, topographical maps, plans of defenses, etc., but it is considered that, owing to changes in shoals and channels, a survey is necessary at this time. The examination will also include a detailed reconnoissance of all ground for possible defenses at forts and islands, and submarine topography as well, with a view to suitable locations of torpedoes for harbor defense.

COMO DISTRICT, NEVADA.—The following charitable suggestion is made by the Virginia *Enterprise:* It would be a good plan to send a party up to Como to see if the miners there are still alive. They went into winter quarters upon their mountain with a good supply of grub, but it has been so long since they have been heard from that no one knows but they may all have been devoured by wild beasts.

Trough Lixiviation.

Mr. Ottokar Hoffmann of Alameda, Cal., has read before the American Institute of Mining Engineers a paper on "Trough Lixiviation," in which he describes a system where he has found that, if chloridized ore is brought into rapid contact with a proper volume of moving sodium hyposulphite solution, the silver chloride contained in the ore dissolves almost instantly, and that it is rather the volume of the solvent than its concentrated state which produces this effect.

Such favorable conditions cannot be attained in tanks. The rapidity with which a certain volume of the solvent can be brought into contact with the ore particles is limited by the speed with which the solution descends through the ore, and thus the leaching-time in tanks cannot be shortened beyond the limit set by the filtering capacity of the ore. In a trough, however, these favorable conditions can be attained by gradually introducing the ore into the moving stream of the solvent. The ore can thus be brought into rapid contact with any desired quantity of the solvent, and moves in and with the stream. The effect is astonishing. Ore charged at the upper end of a trough of moderate length will leave the trough at the lower end desilverized, as tailings, while all the silver chloride will be dissolved in the solution.



O. HOFMANN'S
SYSTEM FOR CONTINUOUS TROUGH LIXIVIATION
SCALE OF FEET
0 4 8 12 16

Solution is performed outside the tanks in troughs, while the ore is moving in and with the stream of solvent, and the tanks are used only to separate the solids from the liquid. The system is a continuous one; but as the lixiviation process requires two solvents, first, water for the removal of the base-metal chlorides, and then a solution of a hyposulphite salt for the extraction of the silver, it has to be divided into two departments: the base-metal and the silver department. Fig. 1 shows a complete arrangement. The upper series of tanks represent the base-metal, the lower series the silver department. The tanks in each department are placed on the same level and close together. They are connected by pipes, *a*, *b*, *c*, *d*, *e*, *f*, *g*, *h*, in such a way as to form a perfect circuit. These connecting pipes are placed a few inches below the rim of the tanks, and also on a level. The diameter of these pipes depends on the daily capacity of the works and the proportion of solvent and ore to be used. Each tank is provided with outlets, *i*, *k*, *l*, *m*, *n*, *o*, *p*, *q*, which are on a level with the connecting pipes. They lead to the base-metal solution trough, which is placed below the bottom-level of the tanks.

Into this trough leads also the outlet *s*, from under the filter bottom. Each tank is also provided in the center of the bottom with a discharge hole, through which the ore is sluiced into the silver-leach trough. The pulp (roasted ore and water) is conveyed from the furnace-house to the base-metal department in a triangular trough, which enters the building near the roof, descends in zigzag, and branches off in two troughs which pass over the two rows of tanks. Over each tank the trough is intersected by a square box, the bottom of which contains one or more plug-holes, in order to permit the charging of any desired tank. By means of slide-gates the stream can be directed to flow in either of the two branches. The sluice-troughs *t*, beneath the bottom of the tanks, all discharge into the silver-leach trough, which leads to the silver department. Here, the tanks are constructed and arranged in exactly the same manner as those in the base-metal department. The solution storage-vats are placed in the base metal building.

Base-Metal Leaching.

The pulp of water and ore, after passing a grinding-machine, in which the lumps are mashed, enters the triangular base-metal leach-trough, and is thus conveyed automatically to the base-metal tanks. The first tank to be charged is *D;* but before commencing operations, the following preparations have to be made. The slide-gate *x* is closed, to direct the stream into the first branch trough, and the plug-hole of the square box above *D* is opened. The connecting-pipe *d*, between tanks *D* and *H*, is closed by a plug from the inside of *D*. The outlets of all the tanks are closed except the outlets *n* of tank *H*. Likewise all outlets from under the filters are closed. This done, the pulp is admitted to flow into tank D. When the solution reaches the level of the connecting-pipes, it will flow through *c* into tank *C*, and when *C* is filled, into tank *B*, and so on until the last tank *H* is filled, when the solution will leave the tank through outlet *n*, *n*. As soon as tank *D* is filled with ore, the pulp is made to flow into tank *C*. The connecting-pipe *c* is closed, and thus tank *D* is disconnected from the circuit. The outlet *s*, below the filter of tank *D*, is opened, and the solution is allowed to drain into the base-metal solution trough. When the solution disappears below the surface of the ore, water is admitted to press out the solution absorbed by the ore. When this is done, sodium hyposulphite solution is applied to press out the water.

As soon as the liquid flowing out through a filter outlet *S*, shows indications of silver, the outlet *s* is closed, and the charge is ready to be sluiced for silver leaching. While tank charge *D* is under the described treatment, which does not take much time, tank *C* is gradually filling with ore. When filled, the pulp is made to enter tank *B*, and tank *C* is disconnected from the circuit and its charge is treated in the same way as that of *D*. Charge *D* being sluiced out with solution, the filter outlet *s* is turned from the base-metal trough in the silver-leach trough, the hose clamp is opened and the solution contained under the filter is allowed to flow out. This accomplished, outlet hose *s* is closed and returned to the base-metal solution trough. Then the plug of connecting pipe *d* is removed and tank *D* is restored again to the circuit. *D* being empty, the flow in the base-metal solution trough will cease until the tank is filled again with base metal solution.

Electric-Light Poles.

At a meeting of the Supervisors' Committee on Streets and Highways, held last week, A. J. Bowie and others, representing the Electric Improvement Co., asked permission to erect poles or masts in the streets for the use of the company's wires. Attorney Van Ness claimed that the company had the constitutional right to erect poles, under the supervision of the Superintendent of Streets, but preferred to obtain permission of the supervisors. The company proposes to extend its wires to the outskirts of the city, and furnish the largest quantity of light for the smallest amount of money. The object of applying to the board for the privilege is to avoid litigation, which might be instigated by rival companies.

In reply to a question by Mr. Barry, Mr. Bowie stated that the company already had a contract with the Harbor Commissioners to light the entire city-front. His company had a capital of $2,500,000, and they intended extending their circuits throughout the city as rapidly as possible, particularly in the residence sections, where they contemplated supplying incandescent lights for household use.

George H. Roe, secretary of the California Electric-Light Co., opposed the granting of the privileges asked for, as in the near future all wires must be operated under ground. He believed there were already too many poles in the streets. Those applying for privileges to place wires along the streets should be compelled to put them underground. The California Co. had already invested $100,000 in running wires above ground which would be sacrificed to replace the wires underground. If their work was begun now, the wires would be placed below the surface of the street.

Mr. Bowie replied that no method yet devised for working wires under ground had proved to be a success. Experiments in Detroit, New York, Philadelphia, Washington, and other cities, of working light wires under ground, had proved failures. The tremendous induction from high currents prevents the working of light wires under ground. Out of 30,000 miles of wire in New York not 6000 are under ground.

Mr. Pilster moved to lay the matter over for four weeks. So ordered.

POTOSI M. CO.—At the annual meeting of the Potosi Mining Co. the old directors and officers were re-elected, consisting of A. K. P. Harmon (President), W. E. Sell (Vice-President), A. W. Rose, Jr., C. T. Bridges and Joseph Marks. Charles E. Elliot was reappointed Secretary, A. C. Hamilton, Superintendent, and Nevada Bank Treasurer. The company was overdrawn at the bank $34,524 on March 1st, but considerable bullion has yet to come in before a balance will be struck. The superintendent's annual report shows that considerable ore has been developed in the mine, and concludes as follows: "It is hoped that the power generated by the electric motor at the Nevada mill may be so far reduced in cost as to afford the mine greater margin on the ore extracted."

UNDERGROUND WIRES.—The entire subject of placing electric-light wires underground was discussed at the meeting of the National Electric-Light Convention on Feb. 21st last. The report of the committee appointed last year was considered, and Geo. H. Roe of the California Electric-Light Company offered the following resolution: "That, while the appliances and devices for operating electric-light wires underground are being continually improved, and promise ultimately to render practical the operating of all electric-light wires underground, they have not yet reached such a degree of perfection as would justify this convention in declaring itself in favor of underground wires for central station arc lighting.'—*Western Electrician, Feb. 23d.*

THE COPPER SYNDICATE.—George F. Coppins, vice-president of the Brass Manufacturers' Association, says: "The present high price of copper affects us very greatly, and we hope for the failure of the great copper syndicate. From $18,000,000 to $20,000,000 worth of copper is now being carried by the syndicate, and it is said that they have too great a load to safely carry. They have established a bank at Paris which is backed by the Rothschilds. If the trust should break it would please all the brass manufacturers only too well."

SMELTER IN OREGON.—A dispatch from Portland, Oregon, states that the Chicago company which intended to erect smelting works at Tacoma have changed their minds and will put it up at Portland instead. A site has been secured where they will have the use of three overland railroads. It is expected to have the smelter in operation this summer. Major Delashmutt and other large mine-owners at Cœur d'Alene have offered to contract to deliver 400 tons of ore at the smelter per day.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Cor. *Ledger*, March 16: There is jubilation over the bountiful rains which have fallen the past week. Instructions have been received from the managers of the Wildman M. Co. in the East to add 10 more stamps to the mill as soon as possible. The last sinking of 100 feet is completed, and a drift has already been started at the 700-foot level. The mine continues to look more encouraging as they get deeper. The material for the additional stamps to the mill will be delivered just as soon as the weather will permit. S. D. R. Stewart is making preparations for sinking a shaft near the old Lincoln mine, and is having the hoisting works moved from the McAdams claim to the new shaft. Good rock has been discovered in that location.

NEW MINING CO.—*Ledger*, March 16: The South Eureka M. Co., comprising Dr. J. L. Mayon, J. F. Parks, Jackson Dennis, U. J. Hussey and I. N. Templeton, has been organized to work the well-known mining property known as Tanner's hill and extending 2000 feet along the mother lode, from the Summit to the Oneida mine. The Plymouth Con. is running 35 stamps of their mill. The contractors of the Alpi have struck water in superabundance, causing two of the contractors to throw up the job.

COSMOPOLITAN.—*Dispatch*, March 16: At the 500 level the east crosscut is out 260 feet; west crosscut, 110 feet; both the crosscuts have been suspended and are running levels north and south on the ledge; north drift in 40 feet; south drift in 30 feet; north drift on 300-foot level in 80 feet.

EMMA.—This prospect is situated near the Mokelumne river in the Clinton mining district, and about eight miles from Jackson. It is owned by J. L. Madden and Wm. Daugherty, and is being worked by them on a limited scale. They have a tunnel in about 70 feet, and expect to tap the ledge about 100 feet further on. They are now sinking a shaft on the ledge which is about three feet wide at a depth of 50 feet.

DRYTOWN CON.—This mine is going along in a smooth way. The shaft is now ready for the machinery, the pipe is being laid as fast as possible and will be finished next week. The directors expect to have the hoisting machinery ready by April 1st so as to hoist out the water.

GIN MINE.—A party of miners have leased this mine for a short time. They have run a tunnel into the hill about 50 feet, and have struck some very good ore, enough to pay them wages for all the dead-work that has been done.

GOVER.—The Gover mill is running on some very fine ore taken from level 2. They make about one ton of sulphurets per day that will work $180 to $200 per ton. The Gover has many setbacks, but masters them all.

OVERPLUS.—At Quartz Mountain are running their Huntington mill on the same quality of good ore. It nets the owners about $1000 per month.

NORTH CALIFORNIA.—Are running on much better ore this month, taken from near the shaft in the North tunnel.

Butte.

FROM CHANNEL POSTOFFICE.—Cor. Oroville *Register*, March 9: Times are very dull, as some of the best paying mines in the vicinity are shut down; but it is an old adage "It's an ill wind that blows no one any good," so it is with mines shutting down. It has thrown many miners out of employment, and consequently they have gone to prospecting, and that branch of the mining industry is very lively. A few fine prospects have been struck, but nothing worthy of note of late but what has been reported to the Oroville papers. Some of the old prospecting enterprises are pushing ahead with their work in a vigorous manner, among which is the Alki mine of which Geo. Parry is the superintendent and principal owner. They have driven several hundred feet of incline and added some valuable improvements to their pumping and hoisting machinery, which leaves no room to doubt that they are in earnest, and that they are going to reach the bottom of the Old Pliocene, or, as it is called here, the "Big Channel," of which so many ineffectual attempts have been made to find the bottom. When once the bottom of this is reached, there is no doubt but what they will have one of the richest mines in the State. The Miocene, owned by Sparks, Henderson & Morris, situated some distance above the Alki, is having a tunnel driven upon it, and the indications for rich pay are very good. The owners of the Calamity mine are also driving a tunnel with a very good showing at present. The Hidden Treasure Co. are at present prospecting their quartz ledge near Toad Town, and I think it will prove one of the best in this county in a short time. This company will resume work on their gravel mine, situated three miles east of Old Lovelock and adjoining the Alki and Calamity mines. The Oro Fino, owned partly and managed by Mr. T. Smith, is making a fine showing. I saw one nugget a short time ago taken from that mine that weighed a few cents less than $400. This and several hundred dollars in fine gold was all taken out in one or two weeks, which shows what can be done on Magalia Ridge with energy and capital to back our efforts. The Wiley Bros. have organized a company in Stockton and started up on Middle Butte to tap the Big Channel. May their efforts be crowned with success is my wish. Messrs. Matlock and Gable, the owners of the Boomerang, have been doing some valuable work on their property in the way of building and also in driving their tunnel ahead. They have concluded to put on hoisting machinery as soon as possible.

Calaveras.

MILL.—Amador *Ledger*, March 16: Donnelly & Howard of Sutter Creek are building a six-stamp mill to go to the Riverside mine, Calaveras county. C. O. Mitchell is making about 1000 feet of 11-inch pipe, which in addition to the 1000 feet the company has on hand at present, will be laid across the Mokelumne river by the canal company for the purpose of running the mill.

El Dorado.

EQUATOR MINE.—Placerville *Observer*, March 13: This mine is situated in Diamond Springs mining district, about five miles south of this city, directly on the mother lode. There are three parallel veins running through the ground belonging to this company. They have several locations. They have two tunnels, one in over 350 feet, and one nearly 600 feet long, besides several inclines run down on the angle of the vein which dips to the east at an angle of 60 degrees. They have recently run into a gold-bearing ore body nearly 20 feet wide. Supt. Burdick, who is not over-enthusiastic without reason, expresses himself as highly encouraged with the general outlook. This property is favorably located for economical working, and its future is looked forward to with much interest.

STILLWAGON MINE.—Supt. S. A. Lane, of the Stillwagon mine, was in town last week. Machinery is now being placed on the ground for the erection of a new mill at that mine. Good ore is reported in the face of the tunnel and a full force of men is now at work.

CRYSTAL MINE.—The tunnel at the Crystal mine is being driven with full force, and it is thought that the ledge will be reached before long, as the rock is changing in character, showing more the nature of wall rock.

BIG TUNNEL.—The Big Tunnel is now in 520 feet. They have just run through a vein of very fine slate 56 feet wide, and are now in ledge matter.

MOUNT PLEASANT.—Capt. Smith set a few men to work on the Mount Pleasant mine at Grizzly Flat on Thursday of last week.

PACIFIC MINE.—The water is lowering rapidly in the Pacific shaft. We expect to see ore coming out before long.

GRAVEL.—Georgetown *Gazette*, March 16: Robert Murdock was down from the gravel mine worked by himself and Denver Craig, near Volcanoville. They report the mine looking up, and are highly elated over the fact that the gravel they are now working is getting richer as they penetrate.

SLIGER.—The Sliger mine, situated near Spanish Dry Diggings, known as the Simpers claim, has been taken hold of by a S. F. company who are constructing a roadway from Spanish Dry Diggings. In a few weeks they intend to put a force of men on and make this one among many of our North Side mines.

Inyo.

MINING NOTES.—*Register*, March 16: At the Lucky Jim, Darwin McKenzie has just started a new steam hoister. He is employing six or eight miners, and making movements for an all-summer work. At Cerro Gordo a few chloriders are working. Boland & Gorman's new venture is essentially a dry concentrating process of fine dust, which is shipped to Melrose. The quantity is immense. Lower freight rates help this new scheme along very materially. Lookout is beginning the season's work in splendid style. Water mains are being relaid all over the hill. At the Minnietta, particularly, Frank Fitzgerald is beginning on the production of two tons daily of concentrates. He wants good miners and some active teams, too, and such can depend upon finding employment.

Mariposa.

A RICH STRIKE.—*Gazette*, March 16: Charles Myers and C. A. Schlageter have struck a rich vein on Bear creek, about four miles north of J. H. Malone's, and not far from the Feleciana mine. The ledge averages from 20 inches to six feet wide, and it all prospects well. Competent judges have tested the rock and declare it a good mine. We are always glad to hear of new veins being discovered and we hope the lucky ones of this may prove it to be a veritable bonanza. The plant was stocked with provisions and a working force this week, and we presume that the next few weeks will determine the definite character of the ledge.

Monterey.

CROOKSHANK MINES.—San Jose *Mercury*, March 12: F. T. Childs, a miner, has returned from the Crookshank mines, 60 miles south of Monterey, and says he thinks that region remarkably rich. Over a hundred claims have been located since January, and five new ledges opened up. The mines are located 40 miles west of Kings City and are three miles from the coast. At present a three-stamp mill and an arastra are doing all the reducing work, but a San Jose firm is going to put in a custom mill for the benefit of those miners who cannot afford to erect a mill. The fact that all goods have to be carried 30 miles from Kings City and then packed the rest of the distance is the reason the place has not been much heard of. The county is to put a road in soon, however, which will facilitate ingress and egress. Mr. Childs says the Crookshank ore assays from $2000 down to $30 or $40.

Napa.

SHIPMENT OF BULLION.—*Independent Calistogian*, March 13: On Monday last, five bars of gold and silver bullion were shipped by the owners of the Palisade mine near Calistoga, to San Francisco, Wells, Fargo & Co. of course having charge of the metal. The weight was 512 pounds. We could not ascertain the value, but it was of course several thousand dollars. The bars attracted a great deal of attention when brought to the express office, as is usually the case here when it is known that bullion is shipped.

Plumas.

SPANISH RANCH.—Cor. Plumas *National*, March 9: Bedrock cleaning on Gopher Hill is in full blast. Messrs. Patten, Duncan & Co. are up from the lower country, and will likely start work on Ohio Point quartz mine. They are also taking a look at the McGowan ledge. Mr. Cameron of Oakland, the new superintendent, is pushing work on the French Ravine ledge, which is showing up finely. The Hallsted Bros. are taking out quartz on the Rich Gulch ledge, and will start the mill in a short time. This will be a good year to prospect, and no doubt much of it will be done.

Shasta.

HYDRAULIC MINES STOPPED.—Shasta *Courier*, March 16: The closing down of the hydraulic mines of Western Shasta is a most infernal outrage on the part of the Government officials. The amount of debris that reaches the Sacramento river from these mines is very trifling and immaterial, and the water in the river flows discolored below the mouth of the streams on which the enjoined mines are located. All of these mines are on clearly mineral land, and some of them on land bought as mineral from the Government. What did the owners of such land purchase them for except to mine upon them—to extract the gold by practical appliances? If the Government goes back on these purchasers, who have been at great expense in fitting their mining property for proper working in addition to having paid for their land, then we say that the Government is guilty of obtaining money under false pretenses, is a fraud and practically a thief.

RICH.—The Sierra Buttes Mining Co. is pushing its tunnels on the Uncle Sam mine on Squaw creek. A new tunnel has tapped a nine-foot ledge of free-milling ore, very rich. This company knew what it was about when it paid Jack Conant $150,000 for the mine.

Sierra.

WATER SUPPLY.—*Mountain Messenger*, March 16: The recent heavy showers have given an abundant supply of water for our miners, enabling the Young America and Sierra Buttes Co.'s to continue work, and the Buffalo and others to resume operations. The Salinas and Mercer is also reported as having sufficient water to run, and also the Keystone.

Siskiyou.

RIVER MINING.—Yreka *Journal*, March 16: The mines are being opened up again in the Salmon River section for spring and summer work. Mr. Ball, of the old Klamath mine, now known as the Golden Ball quartz mine, has struck a rich find. Mr. James, whose claim has been frozen up during the past winter, has again resumed operations. His drifts have been very productive in the past and it is hoped will turn out this year very satisfactory. Messrs. John Doherty and John Barry are also working a rich vein in the Only Chance claim. Messrs. Schroeder & Werner will commence work again for the spring and summer at their quartz mines on Deadwood, this week, and in a short time will add new and additional machinery, to increase the crushing capacity of their mill. They need about 20 hands and have secured several already. The amount of quartz in sight is sufficient to keep a ten-stamp mill in operation for the next 20 years, all of it paying very satisfactory. The placer miners on Humbug creek are not doing much at present, waiting for storms to furnish water, but the quartz miners are busy taking out quartz. There will be more extensive operations in quartz on this stream, during the coming spring and summer season, than for many years past. The river miners on the Klamath are all making active preparations to commence building wingdams, by getting out the necessary timbers, besides having lumber hauled from the sawmills. A number of mines bonded in this county are to be worked on an extensive scale during the coming summer, by the addition of new machinery and plenty of help.

San Diego.

MINE SOLD.—Los Angeles *Mirror*, March 16: C. E. Whelpley, of the firm of Whelpley & Southworth, has just returned from the Julian mining district, San Diego county, whither he was accompanied by D. C. Kling, a mining expert of St. Louis, Mo. Mr. Kling, who is himself an extensive mine-owner in Nevada, purchased from Mr. Whelpley, for a St. Louis syndicate, the Kentuck mine at Banner, five miles below Julian and 65 miles from San Diego, the price being $25 000. The Kentuck is a gold-quartz mine and was worked years ago by a man named McEwing. It has lain idle 10 years. There is one shaft down 160 feet and several others 100 feet, with dozens of drifts and crosscuts. The ledge, which is well defined, is eight feet wide at the bottom, and samples of ore show free gold. The syndicate proposes to begin work as soon as possible.

Trinity.

RUSH CREEK. — Trinity *Journal*, March 16: Messrs. Ehrman & Hancock, as soon as weather permits, will run in a tunnel on the ledge discovered on Rush creek some time ago by Henry Ehrman. The vein is from 6 to 7 feet in width and carries free gold; the ore is not high grade, going from $8 to $10 a ton. The ledge is about one-quarter of a mile from Paulsen's store. There are a number of small ledges in that vicinity, all of which carry gold, but nothing permanent has been discovered yet. The chances of ultimately developing in them something of value are very good. John Anderlina and J. W. Hancock have invented a stamp quartz-mill. The model is simple and looks as though it would work well. They will apply for a patent.

Tulare.

GARNETS.—Visalia *Delta*, March 14: A discovery of the genuine garnet of the pyrope variety has been made lately by Mr. O. D. Barton on Rattlesnake creek in Drum valley, this county. The specimens left in the *Delta* office are small, but we have no doubt that a ledge exists in the same locality, where a species of this precious stone is found in larger sizes. A more common variety is found in large ledges in the vicinity of Three Rivers, this county.

Tuolumne.

PROVING RICH.—Tuolumne *Independent*, March 16: The Mandich Bros.' claim, between Volcano and Sutter Creek, gives promise of proving a bonanza. The shaft is down 45 feet, the vein varying from four to nine feet, and growing larger and increasing in prospects as depth is attained, showing considerable free gold in the rock. They have their tunnel in 120 feet, all on the pay shoot, and with a 400-foot tunnel can tap the vein 300 feet from the surface. There is plenty of timber and free water. On the extension claim, which has been prospected, the show is as good as on the original location. John Paul Dart of Sonora is a partner in the extension.

NEVADA.

Washoe District.

BEST & BELCHER.—Virginia *Enterprise*, March 16: Quartz that carries some metal is being found on the 350 level.

CON. CAL. & VA.—The usual quantity and grade of ore is being extracted from the various openings on the 1400, 1435, 1500, 1600, 1650 and 1950 levels. The stopes on the 1650 continue to look well and are yielding a large amount of ore. The usual quantity of ore is being shipped to the river mills, and the average of the battery assays will be about the same as last week. Both river mills can now be run to their full capacity.

CONFIDENCE.—The west crosscut on the 1300 level is in vein material of a promising appearance. A good deal of prospecting is being done in various parts of the mine. The ground has a fertile appearance and all indications are good for finding paying deposits of ore. The ore shipped to the Brunswick mill averages about $27 a ton. The first bullion shipment sent below on March account amounted to $16,466.05.

HALE & NORCROSS. — The continuation upward of the 500 level ore body, where found on the 400 level, is showing well. Good ore is being found in the upraise from the 500 level. The connections between the 500 and 600 levels give a good circulation of air in the ore stopes. The shipment of $34,673 55 brought the total for the month of February up to $78,097.77.

CHALLENGE.—The top of the joint Confidence raise above the 1100 level continues in clay and quartz of a promising appearance. The joint west crosscut on the 300 level is in vein material of a favorable appearance. The ore is being shipped to the Brunswick mill, and averages $27 a ton.

CROWN POINT.—The raise from the 800 level crosscut is in ore that shows some high assays, but it only averages a low milling grade. A great deal of ore is found on the 400 and 600 levels. On the latter some very rich ore is being found. Are shipping weekly nearly 900 tons of ore.

SAVAGE.—Are shipping over 500 tons of ore a week to the Rock Point mill. The battery assays average nearly $20 a ton. Have shipped bullion of the value of $10,531.20, making the bullion product of the mine $29,066.16 for the month of February.

CHOLLAR.—The usual amount of ore is being extracted, and a great deal of prospecting is being done at various points. The Nevada mill is now doing good work. Now that water is abundant they will be able to start up the whole 60 stamps.

BELCHER.—The east crosscut on the 200 level is passing into material that carries some promising streaks of low-grade quartz. Some prospecting is being done on the 1300 level.

OCCIDENTAL.—Ore is being obtained on the 300, 350 and 450 levels. Some favorable quartz is being obtained on the 650 level. Good progress is making in the grading of the site for the new 20-stamp mill.

OVERMAN.—The stopes are yielding the usual amount of ore, which is being worked at the Vivian mill. On the 6th inst., bullion to the value of $9171.16 was sent below.

YELLOW JACKET.—A good deal of prospecting is being done, and the material encountered promises well. On the 300 level some good ore is showing.

BALTIMORE. — Are still finding a considerable amount of ore of a good quality on the 300 level west, all of which is being saved for reduction.

NORTH OCCIDENTAL.—Work is being done on the 250, 350, 400 and 450 levels. On the 250 level some ore of low grade is being found.

SIERRA NEVADA.—A considerable amount of prospecting is being done and some ore of low grade is now being encountered.

UTAH.—The incline winze below the 600 level is in a formation of quartz and porphyry that shows metal.

ALTA. — The ore producing sections of the mine are yielding all the ore that the mill is capable of working.

SILVER HILL.—The shaft is being put in order preparatory to resuming work in the old lower levels.

POTO I.—The ore-producing sections are looking well, and a good deal of prospecting is being done.

GOULD & CURRY.—On the 450 level the south drift is in a quartz formation that gives low assays.

SEG. BELCHER.—Good progress is being made in the new west crosscut on the 1300 level.

JUSTICE.—The ore stopes are looking well and the mill is kept going to its full capacity.

UNION CON.—The north lateral drift is in a mixture of quartz, clay and porphyry.

CON. IMPERIAL.—The work now being done is principally in the way of repairs.

MEXICAN.—The west crosscut is in vein material that carries some metal.

OPHIR.—The raise above the 1465 level is still showing some metal.

BULLION.—Explorations are still continued on the 500 and 600 levels.

ANDES.—Are extending the drifts on the 175 and 350 levels.

SCORPION.—Are still pushing the crosscut on the 300 level.

Eureka District.

MAY START UP.—Eureka *Sentinel* March 16: The Eureka Con. Co. will soon receive some 700 tons of coke, several carloads of which arrives by every train. This indicates that their furnaces will start up in the near future.

Palmetto District

ACTIVE.—Cor. Esmeralda *News*, March 16: Palmetto is still active, 15 men being employed at the mine. Five stamps will be added to the mill, also concentrators, when Palmetto will become one of the prominent bullion-producing camps of the county.

Silver Peak District.

CLOSED DOWN.—Cor. Esmeralda *News*, March 16: The Silver Peak mines, owing to some unforeseen reason, are shut down once more. Mr. Brunton, the representative of the owners, had just arrived from London, where all arrangements had been made for the sale of the property to the English company. According to mining experts, the gold mines at Silver Peak are the largest on the coast, although the ore is of low grade. To make up that deficiency, there are mountains of the precious metal. It is estimated that if the property should be sold, together with the erection of a mill and supplying the same with water-power, the cost involved would amount to about $1,500,000.

Sunrise District.

PROSPECTORS.—Virginia *Chronicle*, March 13: A party of four prospectors left Sunrise district to develop a mining location made there last year. There is a shaft 250 feet in depth on the property. The shaft is timbered with cedar cut in the vicinity and put in place without squaring it or even removing the bark. Although the timber was placed there 25 years ago, it shows no signs of decay. The shaft is caved some distance above the bottom and will be cleaned out to ascertain the size of the vein, ore

from which assaying above $90 per ton is scattered about the dump near the shaft's mouth.

Tuscarora District.

BELLE ISLE.—*Times-Review*, March 16: West crosscut, 250-foot level, extended 20 feet. Rock in the face somewhat harder, with spar seams coming in.

COMMONWEALTH.—225-foot level: Drift from No. 1 winze has been extended 8 feet, all in ore. Stull timbers are being put in already for stoping. No. 1 upraise has been carried up 9 feet, and will connect with No. 2 east lateral winze within a day or two. South drift from No. 1 west crosscut has been extended 16 feet. 300-foot level: No 1 west crosscut has been extended 15 feet. South drift from No. 1 west crosscut has been advanced 16 feet, cutting seams of high-grade ore.

NEVADA QUEEN.—The stopes have changed but little since last report. Average assay of concentrating ore hoisted during the week has been $18 per ton. The concentrating works are doing well and run steadily. The ore chutes and tracks at the mill are being put up as fast as possible, and the mill will start up on or about April 1st.

NAVAJO.—No. 5 upraise, 350 level, has been carried up 10 feet, and a drift run therefrom 10 feet on the vein, showing a good width of high-grade ore. The usual quantity of ore has been sent to the mill. The various stopes are looking well.

COMBINATION SHAFT.—The Combination shaft has been sunk and timbered 15 feet. The rock is growing harder and shows faces of ore. The north drift from the Commonwealth line, 150-foot level, extended 18 feet.

GRAND PRIZE.—400-foot level: Face of south drift advanced 13 feet and shows 2 feet of good concentrating ore. East crosscut from south drift extended 14 feet.

FOUND TREASURE.—The pump has been run every second day. There has been some decrease in the water during the last two weeks.

NORTH BELLE ISLE.—North drift, 500-foot level, extended 15 feet. The stopes above the 300-foot level show some first-class ore.

ARIZONA.

REPORTED STRIKE.—Tombstone *Epitaph*, March 16: Another reported strike in this district, this time being nearly two feet of between $600 and $700 ore in the Nicholas mine. Well, it is said that many rumors will make a war, and perhaps many rumors will make a genuine strike in Tombstone after awhile.

COLORADO.

THE CARBONATE CAMP.—Denver *Republican*, March 16: The Leadville district is in better condition at present than at any time in the past history of that wonderful mining camp. Unless a reaction should set in, which is not probable, Lake county will produce more silver and lead this year than during any 12 months since carbonates were first discovered there. The daily output now, for six days in the week, is placed at 1600 tons a day, over two-thirds of which is fine silver-bearing ore. This vast production is destined to show immense values for the mines at the close of the year, and instill renewed confidence in the district. The mining operations of Lake county are also upon a more substantial and satisfactory basis, insuring a steady increase in mining and greater stability to the industry. There is a great deal of money behind the leading mining enterprises of the district at present, as well as experience and determination, the three constituting a combination that cannot fail to prove successful. Nearly all the mining and prospecting companies working in the county are well provided with funds, and a great deal of new exploration work is in progress, much of which will be continued to a successful conclusion. Considerable leasing is still being carried on in the district, but this character of mining has passed into more reliable and competent hands. The majority of lessees now working are intelligent, practical miners of business experience and mean to carry their ventures through. The failures and business stagnation of Leadville 60 to 90 days ago were unquestionably due to a general abuse of the tribute system. For a time leases were let by mining companies to miners indiscriminately, and irrespective of their financial means or business ability. As a consequence merchants and professional men were called upon and induced to advance capital and maintain these incompetent leasers. Other tribute works used the fact that they were working under lease to secure heavy and extended credits. Failure necessarily followed incompetent work, and the merchants all lost heavily, and a dozen or so of the smaller dealers failed. The lesson was an expensive one for Leadville people, but it will not be forgotten. The experience shows that the average practical miner is invaluable in his place, but the simple knowledge of how to wield a pick or hammer is not sufficient to find ore or operate a mine economically.

DAKOTA.

BALD MOUNTAIN. — Deadwood *Pioneer*, March 16: Dick Richards, down from Bald Mountain yesterday, is enthusiastic over an ore strike in the Eclipse. Work was resumed a few days ago in an old tunnel on the property, and had progressed only five feet when the ore was first struck. Dick, who is interested in the Ruby Bell and other well-known properties in Ruby, states the Eclipse is the best mine in the camp. The most favorable reports are heard from the Diamond Queen. The company has just completed a 100-foot tunnel, which has crosscut two distinct ore ledges, one five, the other 15 feet wide. One of the directors, who visited the property Tuesday, states that were reduction works operating, his company alone could supply all the ore required to run them.

IDAHO.

CLAYTON.—Cor. Idaho *Messenger*, March 12: Clayton is located in the heart of a rich mining region, and is about 30 miles from Challis, the county seat of Custer county. It is walled in on either side by mountains and traversed by the Salmon river the entire length. The Ella mine is looking well, and it is expected daily that the big ledge will be struck in the lower tunnel. The Silver Rule, on Slate creek, 12 miles above Clayton, is working about 50 men, its showing is good, and promises to be one of the best, if not the best mining propositions in the Territory. The Cinnabar, on Slate creek, will start up in the spring with a large force of men. This is the mine that was formerly owned by the Kirk Bros., and was stocked by Eastern parties, a few months ago, for the sum of $2,000,000. The smelter will start much earlier this spring than usual, as the roads are in good condition for heavy freighting at the present time. The present encouraging outlook for Clayton indicates a "big boom" there next summer.

LOWER CALIFORNIA.

CONFLICTING REPORTS.—National City *Record*, March 14: During the last few days several of those who recently left for the new gold-fields in the Santa Clara valley, Lower California, have returned, but it is hardly possible to come to any definite conclusion as to the outlook at present or the possibilities for the future, from what these people report, on account of the wide diversity of their respective stories. Some of the disappointed ones tell very discouraging tales and come back richer in experience only, but poorer in pocket, while others confirm the news of last week, and state that the mines are all they have been claimed to be, backing their statement with the announcement of their immediate return to the camp. It is just possible that the grumblers are not the right kind of people to be successful in a mining camp, and have not given the placers a sufficient trial, but nevertheless their woeful tales and the sincerity with which they are given should serve as a warning to all who had exaggerated ideas of the ease with which fortunes are made by inexperienced men in the mines. It is apparent that the canyons in the Santa Clara valley are gold bearing, and it is established beyond a doubt that rich finds have been made there, but only to the patient worker comes the reward, and even he is often unfortunate and cannot strike "color" during months of hard labor. The report of three well-known citizens of National, who returned from the camp on Monday and leave again for there to-day, follows. It bears the stamp of truth and is reliable. It is not published to induce any one to start for Lower California or to advertise the mines, but simply as the best and most authentic report so far received from the new camp by the *Record*. On Monday afternoon J. C. Crenshaw, Capt. Sam McHenry and John E. Clouse arrived here after a 52-hour trip direct from the new mining camp in the Santa Clara valley. Their arrival created much excitement, owing to the fact that they were the first party of nationalities who returned from the diggings with reliable information. Their report, while conservative and not at all sensational, is a highly satisfactory one, and proves beyond any possibility of doubt that the prevailing excitement is founded on bonafide facts, and that the new El Dorado is indeed destined to become a great mining camp. Mr. Crenshaw, to whom the *Record* is principally indebted for the following information, is most positive in his assurances of the richness of the mines, and he, as well as those who came with him, will at once return to the camp. It is learned that the roads to the camp proper are in a very good condition and that contrary to prevailing impressions, wagons can easily travel all the way through. The weather is not nearly as cold as reported, the days being mild and only the nights being considerably colder than here. There is no snow in or near the camp. The placers are located in four gulches, which join into each other and are called Mexican gulch, where the first discovery was made, the American gulch, the Indian gulch and the Alamo gulch. The Judges' tent and the Mexican soldiers are located in the American gulch. These ravines are many miles long and afford ample room for thousands of prospectors and miners. On Saturday afternoon last about 1000 people were in the mines, about one-half of them being actual workers with located or denounced claims. Since then people have departed for there at a rate of about 200 per day. All who work persistently make more or less money and rich finds are daily occurrences, but there are many people there who work only a few hours, expecting to find a pocket at once, and of these, the gambling, dissatisfied element is composed. Many of that class will probably shortly return and give the place a black eye by denouncing it as no good. The camp is a very orderly one, although liquor is sold there, and the best of feeling exists between Mexicans and Americans. The Mexican judge is impartial and just and the soldiers act as police, keeping everybody and everything straight. Provisions are plentiful, although, with the exception of fresh beef, which is 12½ cents per pound, they are high priced. Flour was quoted at $12 per 100 pounds last week. Firearms must be left in the camp, and individuals are not allowed to carry them around.

MONTANA.

A SMELTER FOR CASTLE.—*Mining Review*, March 16: Mr. I. N. Knight, a prominent mining man of the Castle Mountain district, has been in the city during the past week on business looking toward the future prosperity of his particular section of the country. Mr. Knight is very anxious to establish a custom smelting plant in Castle, and claims that a 60-ton smelter would experience no difficulty whatever in securing ores to keep it constantly employed.

UTAH.

REVIEW.—Salt Lake *Tribune*, March 15: The week has been a quiet one in mining circles; no special event marks it, but the general outlook is very fair. The receipts in this city for the week ending March 13th, inclusive, were to the total value of $110,159.33, of which $44,635.33 was in ore, and $65,524 was in bullion. For the previous week the receipts were $113,458, of which $62,658 was in bullion and $50,800 was in ore. The product for the Ontario for this week was of bullion, 22,715 68 fine ounces; from ore sales, $24,581.21; an approximate total of $47,296.89. The Daly output during the week was from ore sales, two lots, $15,899.87; no bullion. The Horn silver prospects are growing better; its ore product is fair, and the prospects in the new shaft are encouraging. Fine bar receipts in this city for the week were to the value of $23,815; base bullion, $20,459. The Hanauer smelter produced during the week bullion valued at $21,250. Ore receipts here for the week were $16,835.33 in value by Wells, Fargo & Co.; $27,800 by McCornick & Co.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, March 21, 1889.

General trade was quiet up to to-day, when more activity is noted in all lines, due to clear skies and a more hopeful feeling regarding the future. Houses having salesmen on the road report stocks generally held by interior merchants to be light, which will necessitate early replenishing. Among iron-workers business continues light, but they are buoyed up by the confirmed reports that with more settled weather many orders for work will be placed. The outlook favors the belief that when business does open with them, it will prove very active.

The local money market continues to shape itself to easier terms for borrowers. The commercial and savings banks report, as a rule, deposits increasing and only a fair call for funds. There is a more general disposition to draw funds from the East for use in this city. It is claimed that there is a lessened call for funds from the country, which, it is affirmed, goes to show that interior local capitalists are more disposed to loan money on realty than when the weather pointed to a dry season. The call for money for speculative purposes continues light, as the light trading in futures on Call and in local and mining securities indicate. It is claimed that soon after more settled weather is had, there will be quite a revival in the speculative markets, and consequently a freer demand for funds.

The lumber trust has advanced prices, which will probably tend to delay many contemplated improvements. On the 14th instant the pine men made a general advance of $2 per thousand. On the 15th inst. the retailers made an advance of $3 per thousand. The redwood men are inclined toward an advance. Manufacturers are talking higher prices.

The steamship Belgic sailed to-day for Japan and China, taking out the following treasure: Mexican dollars, 216,744; gold coin, $11,101; and silver bullion, $150,000. Total, $377,845.

SILVER—The market does not show as much firmness in comparison with prices ruling up to two weeks ago. This is due to a decline in exchange on New York. For shipment by the last steamer sailing for China there was only one buyer, and in consequence the prices paid are said to have been about one-eighth of a cent below New York prices. The output of the mines on this coast is still light.

MEXICAN DOLLARS—There was more doing the past week, owing to a fair demand for shipment to China. Prices paid ranged from 73 to 73¼c, although sales in a small way were made by dealers at a slight advance.

QUICKSILVER—Another shading in prices is reported. The demand is still slow, although the outlook is favorable for a large increased consumption in the near future. In last month there was over 216,000 lbs. sent overland from this city.

LEAD—The market continues fairly active, with Alaska and Sacramento canners the chief buyers of pig. Values remain unchanged, although a slight shading is said to be obtainable by a large buyer.

TIN—The imports of tinplate the past week aggregated 1003 boxes from New York by "rail." The market is steady at full prices for both spot and prompt loading. The call is quite good, chiefly from Alaska and Columbia river canners. Advices from England report a syndicate forming on the part of American buyers to control the production of tinplate in South Wales.

BORAX—Receipts the past week aggregated 182,000 lbs. The Charmer for New York took out 788,744 lbs. The market is steady.

IRON—Imports the past week aggregated 300 tons of pig from Puget Sound. The market is dull but steady. The stock of foreign here and to arrive is ample to meet all requirements for several months to come, unless the consumption should enlarge. The output of the Oregon Iron Co. and of the Puget Sound Iron Co. is chiefly under contract. The bulk of the former is used in Oregon, while that of the latter is taken here.

COAL—Imports the past week aggregate as follows: Japan, 1340 tons; overland, 283; Wellington, 4700; Australia, 2744; and Nanaimo, 4073. Total, 10,440 tons. The market is weak and in buyers' favor, which makes it difficult to give exact quotations. The South Pacific Railroad Co. will have, in connection with their sailing vessels from the Sound, two steam colliers in service between this port and their mine in British Columbia. By this means they can not only supply their own wants, but have a small surplus to sell to their employes at cost prices. The yards in this city are full, while large consumers have supplies to meet their wants for several weeks to come. Mail advices from Newcastle, N. S. W., report that the tonnage in port and listed to arrive for this port was comparatively small, but cable advices report that improved wheat crop prospects in this State will send more vessels here.

COPPER—The market the past week did not show any material change. To sell, low prices had to be accepted, but from 15 to 16c had to be paid in New York. Many large consumers at the East have contracted at 16½c up to June next, while others have good stocks on hand.

Eastern Metal Markets.

By Telegraph.

NEW YORK, March 21, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42½	93	$15 50	$3 72½	$21 40
Friday	42½	93	15 50	3 75	21 45
Saturday	42½	93	15 60	3 72½	21 30
Monday	42½	93	15 25	3 70	21 00
Tuesday	42 9-16	93½	15 00	3 72½	21 05
Wednesday	42⅝	93⅝	14 75	3 70	21 20

NEW YORK, March 21.—The past week has been very quiet in copper, owing to the uncertainty regarding the future. The prevailing opinion among the better informed is that from the ruins of the French syndicate, a new one will be formed, which will be stronger in every respect than that one gone to the wall. Holders of copper have not forced sales, but express considerable confidence in the future. Tin has fluctuated some, closing easier. Lead has moved to a fair extent. Large consumers buy sparingly.

San Francisco Metal Market.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY CO.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING MARCH 12, 1889,

399,374. — ARTIFICIAL SLATE — Calvin Brown, S. F.

399,515.—BRAKE—John Fulton, Biggs, Ogn.

399,524.—COMPOUND CABINET ENGINE—E. W. Hamlin, S. F.

399,328.—DYNAMO ARMATURE — J. A. Hayes, S. F.

399,615.—ROLLER BEARING—R. W. Hent, S. F.

399,497.—SHIPPING RECEIPT COVER—D. K. Howe, Portland, Ogn.

399 412.—FENCE MACHINE — G. W. Johnson, Dallas, Ogn.

399,337.—WEED-CUTTER — F. E. Lux, Walla Walla, W. T.

399,345.—CAMERA ADJUSTER—H. E. Pohlman, S. F.

399 284.—WALL FOR HOUSES—W. R. Ray, Los Angeles, Cal.

399,444.—FOOTBOARD FOR WOOD-CHOPPERS—A. L. Stevens, Little Falls, W. T.

399,451.—HASP LOCK — W. Tiffany, Creswell, Ogn.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

COMPOUND CABINET ENGINE.—E. W. Hamlin, S. F., assignor to G. G. Wickson. No. 399 524. Dated March 12, 1889. This invention relates to that class of compound engines which employ one steam cylinder and the trunk form of piston head, the working parts being inclosed for automatic lubrication. The object to be attained by this invention is a high grade of economy and proficiency when applied to smaller sizes of compound engines, and especially under a high rate of speed. These engines may be constructed either as upright or horizontal, the results being the same in either case.

CAMERA ADJUSTER.—Henry E. Poehlman, S. F. No. 399,345. Dated March 12, 1889. This invention relates to a means for adjusting and regulating the position of the camera on the tripod; and it consists in the combination of a plate secured on the top of the tripod, a plate secured to the base of the camera and connections between said plates whereby the latter may have an axial movement, a movement forward and back and a movement from side to side. The object is to provide a means for attaching the camera to the tripod of such character that the camera may turn axially and may be adjusted to any inclination up or down, or to any inclination laterally, so that, notwithstanding the position of the tripod, the camera may be properly adjusted.

THERE is some excitement about mining discoveries in the Black Knob mountains, below Sacramento canyon, Nevada.

MECHANICAL PROGRESS.

Steel Castings.

In a paper read before the American Society of Mechanical Engineers, Mr. R. T. Morgan, Sr., said:

All of the conditions specified for castings of iron must be duplicated in the manufacture of steel castings, but on higher and more exacting planes. In the manufacture of iron castings, most of the practice of the world has been carried on (governed in the many conditions necessarily specified here as to the use of mixtures of material) by grades bought from leading producers according to the standards fixed by the breaking and eye test, using cupolas or air-furnaces with coke and coal to do the melting. All the operations depend on the crude tests last specified, and the reliability of the supply of the best materials from reputable manufacturers of coal, coke and iron. A great many responsible, reputable founders, having experienced, practical men employed in their foundries under such conditions, have turned out some of the most varied, complicated and best castings made for years. Some few of the modern and best have had their chemical laboratories, and as far as material is concerned, have gone beyond the general practice of iron founders and are certainly entitled to the best results. But while these show by comparison the possibility of getting the best iron castings, just as wrought iron has been manufactured in rolling-mills under similar crude practical conditions, the manufacture of the many grades of steel required for the best steel castings of varying sizes and kinds has made necessary all the higher conditions of chemical and practical knowledge combined. Steel castings, by whatever method the steel is melted—whether open-hearth, Bessemer, crucible, or some other—require each a different treatment to produce similar results in two different kinds and sizes of castings, following with keener practical care every operation specified for iron castings. After this, practical machine and other testing records should be made, so that every known practical chemical operation shall have been recorded for future use, with a careful watch also upon the practical use of castings made. All this takes time, just as has been necessary for the steel-rail men to find out its necessary good qualities. Steel castings require higher-class conditions than iron, depending more on the chemical than practical, but requiring both to a higher degree for steel than iron. The manufacturer having the best general conditions, and who will have the desire and determination to take none but the best stock, will certainly make the best steel castings. To enable him to do so it will be necessary for him to get the best encouragement possible from the purchaser of steel castings at lowest competing price, but will be willing to pay more for the best castings made under careful and costly conditions than for castings not so good made under inferior conditions. This latter enters into the question as much as either and all of the others.

Steel castings made and annealed well have an average of at least four times the tensile and wearing qualities of best cast iron. With the many conditions specified here carefully attended to, the splendid results attained by leading manufacturers of iron castings in the leading countries of the world are possible, and I have not the least doubt that their success will be fully equaled in time in steel castings. Of this we have many satisfactory evidences already from some leading manufacturers of steel castings, who have turned out complicated examples both large and small.

Does Machinery Run Better at Night?

In an article from the pen of R. James Abernathy, the following is taken relative to the inquiry whether machinery runs better at night:

Very few persons most emphatically declare that there is no difference as between the day and night time operations of machinery, notwithstanding that the preponderance of the evidence, based on actual experience and observation, is against them, and in favor of the oft-repeated declaration that machinery does run stronger by night than by day. At first glance, I would, as a rule, have been as quick to denounce the declaration as a purely visionary deduction of a distorted imagination; but long experience has taught me that all statements or positions, well supported by evidence, will bear careful investigation, and therefore instead of rejecting the question as simply theoretical, I have busied my brain in the discovery of a probable cause for such results, and long since became convinced that the changes in nature, and especially in atmospheric conditions, that are constantly taking place, afford a very reasonable explanation of the proposition. The changed conditions favoring the stronger movement of machinery do not necessarily and always occur at night, but more frequently at night than at any other time; and hence the reason why, by actual observation, machinery is credited with running stronger at night than by day. The favoring conditions do not always occur at night, and sometimes occur during the daytime; but, owing to the numerous duties and activities in which men are engaged during the day, the changes are not noticed so readily as at night, when there is naught to do but watch the operations of the mill.

As viewed by the writer, the causes of the changes in the operation of machinery are largely due to the changes in the weight and density of the atmosphere. Where machinery is propelled by water, there are the most logical reasons for believing that it will run stronger when the atmosphere is what we call "light" than when it is heavy, because as the air grows lighter, water relatively increases in weight, which permits a given quantity of it to do more work in a given time.

We all know that a body will fall in a vacuum with much greater force than it will in open air. A feather will accompany a more solid body in its descent in vacuum, while in the open air it will float off or descend very slowly. So, at least, we have all been taught in elementary philosophy. If that proposition be accepted as a fact, it then becomes evident that as the density of the atmosphere is lessened, the effectiveness of falling bodies is increased in that proportion. Water can perform no work except by falling through space. It seems clear enough that with a minimum hindrance in the way of atmospheric resistance, a maximum amount of work can be performed. Also, machinery can be moved more freely and with less power with decreased atmospheric resistance. With the water relatively heavier and resistance less, why should not the machinery run stronger?—*Western Machinist.*

A ROLLING-MILL FOR ALUMINUM.—As an evidence of the growing importance of aluminum in the arts, it is noted that a new plant of considerable capacity and dimensions has just been laid down at the works of the Oldbury Aluminum Company, Oldbury, England, for the production of rolled sheet, strip, and wire in aluminum, for use by steelmakers, engineers, ironfounders, cycle manufacturers, and others. For sheathing purposes it has recently been found particularly useful. The new plant includes two large rolling-mills, one of which will be set apart for rolling rods and sheets both in aluminum and bronze alloys. An engine of about 100-horse power has been constructed in this mill with a complete set of rolls similar to those used in ordinary forges. A number of annealing furnaces have also been built. It is estimated that this mill, when running full time, will turn out ten tons of finished metal per week. The wire-mill will, it is thought, produce about five tons per week of aluminium or bronze wire. This will have also a separate engine and complete set of wire-drawing appliances. The aluminium wire will be drawn cold, in the same way as brass wire. The sheets of metal will be also rolled cold like sheets of brass and then annealed. A foundry is also provided for supplying these mills with strips and other castings for manufacturing into rods and sheets. The foundry has six furnaces, which will turn out sufficient material to keep both the mills running.

NAILS OF TINNED SHEET IRON.—Scraps of tinned iron have long been a waste product, whose application, for any purpose worthy of the intrinsic value of the metals contained in them, has been an unsolved problem. It is true that scraps of this kind have been cast, but the hardness and granular structure render the metal fit only for use as weights. Also, to a slight extent, the tin has been removed by electrolytic processes. But there has not been any definite use of this product as a material manufacture until its recent use for nails. Scraps of tin are cut by dies into rectangular bits, with a length of about three times their width. These scraps are then fed from an automatic hopper between dies, when they are squeezed first to square form, like a nail, and then headed. Nails of this kind are well fitted for many purposes, being free from tendency to rust, also light, very rigid, and capable of being driven into the hardest wood without buckling.

WHY NOT COMPOUND LOCOMOTIVES?—The Pennsylvania has recently imported from England a compound locomotive, of the design used on the London & Northwestern and other English railroads, where it is meeting with success as to cost of running. No modern steamship is now built without having compound, triple, or quadruple compound engines, which have resulted in an enormous saving of fuel. There should be no reason why the same principle applied to our locomotives should not produce the same results. Evidently this is the entering wedge for compound locomotives on the Pennsylvania system if the results obtained from the "Webb" prove satisfactory. A cotemporary suggests that our American mechanics give this question careful consideration, for, unless we do, our railroads will be going to England for their locomotives.

A NEW PROCESS has been brought out in Vienna for the manufacture of copper-coated steel wire for electrical purposes. The old method was galvanic, while according to the one now proposed, the steel wire will be coated by spirally winding around it very thin copper bands. The object in all such wires is to combine the great conducting-power of the copper with the tenacity of the steel.

THE breaking strain of iron and steel does not (as hitherto assumed) indicate the quality. A high breaking strain may be due to extreme softness. The contraction of area at the fracture forms an essential element in estimating the quality.

SCIENTIFIC PROGRESS.

New Relations Between Light and Electricity.

On repeating the well-known experiments in the perforation of insulating plates by the electric spark with plates of various minerals, Prof. Marangoni has obtained certain curious results. Particularly, with plates of Iceland spar, obtained through a cleavage parallel with the rhombohedron, the following results are obtained: (1) the hole made in Iceland spar by the electric discharge is in a straight line, while in glass it is zigzag; (2) the discharge, instead of following the direction of the planes of cleavage, as might be expected, follows that of the principal axis of the rhombohedron, that is to say, the optical axis; (3) along the aperture there are observed two slits situated in two planes at right angles with each other, and which are intersected by the hole itself, say the optical axis. One of these slits is found in the principal section.

As a general thing, the first spark pierces the plate. Prof. Marangoni experimented with various minerals, such as fluorspar, selenite, muscovite and topaz; but, as the specimens were defective, the results were of no account. A beautiful specimen of rock salt, on the contrary, gave excellent results. With plates parallel with the plane of the cube and varying from 5 to 10 mm. the electric discharge perforated them at right angles with their faces and produced two slits at right angles with each other, and consequently with the faces of the cube, and several other small slits at right angles with each other and bisecting the angles of the first. The smallest slits were therefore in planes parallel with the faces of the dodecahedron.

The facts thus made known have led the professor to conclude on the following relations between the propagation of electricity and that of light:

1. Light and electricity in a medium of regular molecular structure, are propagated in a straight line.

2. Light and electricity, in a minimum of time, that is to say, with the least resistance, take certain directions which are those of the axes of elasticity, or certain directions having determinate ratios to such axes.

3. Light is a transverse vibratory motion, and, in non-isotropic bodies, is decomposed into two rays, so that the plane of the vibrations of one of the rays is at right angles with the plane of the vibrations of the other.

The electric discharge produces slits at right angles with its own direction, and these slits are not, as a general thing, produced according to the planes of cleavage. This would countenance the supposition that electricity also admits of transverse vibrations like light, and might likewise be polarized according to two planes at right angles.

Light, in an amorphous medium, such as glass, changes direction at the least accident, and the trajectory of the luminous vibrations is then very complicated.

So, too, the slit produced by the electric discharge through a plate of glass does not allow of any normal direction.

The facts observed on the electric discharge through crystals are in perfect accordance with Fresnel's theory that the vibrations of ether take place more easily in directions parallel with the layers of the molecules, and that, consequently, every oblique vibration upon one of the axes of elasticity is decomposed into two vibrations, one of which is parallel with such axis and the other at right angles with it.

Prof. Marangoni regards this analogy of effects as a new proof of the hypothesis that attributes light as well as electricity to a vibratory state of ether.—*La Lumiere Electrique.*

IMPORTANT EXPERIMENTS WITH SALT.—N. N. Beketov of Charkof has recently communicated to one of the scientific societies of St. Petersburg the results of his experiments on the electrolysis of common salt. *Engineering* says: All the sodium products are at present obtained by the Leblanc or ammonium process, and several manufacturers have, it appears, applied to Mr. Beketov for an opinion as to the comparative advantages of these processes. Being of the opinion that neither the Leblanc nor the ammonia process was as perfect as it ought to be, Mr. Beketov determined to try electrolysis, though he had already experimented successfully in this direction some years before. This last set of experiments have, it is stated, been more promising, though they have not yet been tried on a commercial scale. The inventor sends a current through a mass of fused salt, the temperature of which is about 500° C. In this condition it is a fair conductor, and is rapidly decomposed by the current. With an electro-motive force of five volts and a current of one ampere, 36 pounds of salt can be completely decomposed in 24 hours. From this the author argues that considerable economy can be effected by the adoption of the new process.

ALIMENT PREFERRED BY PLANTS.—M. Ville, after years of careful experiment and close observation, was led to believe that the aliment preferred by cereals is nitrogen; by leguminous plants, potassa; by roots, the phosphates. Understand these are the preferred elements, but not the exclusive, for these three substances in various proportions are necessary to each and all, and even lime, which humus renders assimilable, must be added. While nitrogen may be preferred by cereals for the formation of the grain, phosphates are necessary. We only give the above points to indicate the preference and a partial necessity.

AN IMPORTANT INVENTION.—London *Iron*, under the head of "Oolite Marble," refers as follows to what is apparently a very important scientific invention: Oolite marble reads like a contradiction, but it is not one; it only denotes a further development of science, by means of which the softest oolitic stone is transformed into the hardest marble. The process by which this is effected consists in treating the stone with a chemical solution in which a powerful acid plays an important part. The solution acts upon the stone to a depth of about half an inch, and becomes incorporated with and forms part of the stone itself, closing up the pores, and giving to the surface a marble-like character and rendering it impervious to damp. It imparts great additional strength to the stone, and produces a face so hard that it can be polished to a surface equal to marble or granite, as we have seen. Some stone prepared by this process was used in building a church five years ago—before the process was perfected—but it is stated that not the slightest sign of deterioration is visible. The process is being introduced by the Oolite Marble Company of 352 Strand, London, and a satisfactory demonstration of its effectiveness took place on Feb. 15. Apart from its application to building stones, the process enlarges the scope for ornamentation and decoration in many important directions in connection with architecture. It is stated that the application of the hardening process does not add 5 per cent to the cost of the stone.

ELECTRICALLY ILLUMINATING STEAM.—In Wiedemann's Annalen, Herr R. Von Helmholtz describes a pretty and singular experiment. A jet of steam escaping from a hole one or two millimeters in diameter is lighted obliquely and observed upon a dark background. The jet is then invisible at the base and whitish at the top. But if a pointed wire connected with a static induction machine be brought near, the jet immediately assumes a brilliant tint, whose color depends upon the potential of the point. The same effect is produced without the aid of electricity by merely holding a heated body near the jet. The phenomenon is due, no doubt, to a modification of the size of the particles of aqueous vapor, and in the hands of Prof. Helmholtz we may expect the experiment to throw new light on some of the most difficult problems of molecular physics. To this the London *Electrician* adds: A. E. Mayor, who at one time held the appointment of chief electrician in the Chilian navy, has frequently observed the effect described when a beam of electric light has been thrown upon a cloud of steam. For naval purposes this plan of blowing off steam and projecting the beam upon the cloud forms a most efficient method of signaling, and in action it is much better than any device involving the suspension of lamps from the yard-arm, since it does not reveal the exact position of the ship to the enemy.

ELECTRICITY UNDERGROUND.—Incandescent lights now light up the underground workings of the Anaconda mine, Montana. They started off with 500 lamps, but more are constantly being added, and soon 1000 lights will be in use. Candles are a thing of the past in that mine. Electric lights will also be used in the hoisting works, blacksmith shops and all shops and buildings about the mine. Supt. Carroll says the electric lamps are better, cheaper and safer than candles. Should a lamp be broken, the moment the air strikes the carbon it crumbles and the light goes out. The whole plant, engines and all, cost but $20,000.

LUNAR INFLUENCE ON THE MAGNETIC NEEDLE. According to M. Ligner, the Austrian meteorologist, as ascertained by careful investigation, the moon has an influence on a magnetic needle varying with its phases and its declination. The phenomenon is said to be more prominently noticeable when the moon is near the earth, and to be very marked at those periods when she is passing from the full to her first and second quarter. It also appears that the disturbances in question are at their maximum at the time when the moon is in the plane of the equator, and greater also during the southern than it is during the northern declination.

TO PREVENT WRINKLES.—A well-known doctor advised a lady who was just beginning to show those odious wrinkles about the eyes to wash her face every night in boiling-hot water, just as hot as she could bear it, in which is a little bicarbonate of soda. She must bathe her face in this thoroughly and hold her face in the steam for some time. After drying the skin it should be well rubbed with olive oil. This prescription, faithfully followed every night, will, he says, not only prevent wrinkles, but will send away those that have already come.

A YALE PROFESSOR'S DISCOVERY.—Prof. Chas. S. Hastings of Yale has discovered a new combination of glasses for the telescope object glass which eliminates secondary chromatic aberration. It is expected to revolutionize astronomy. The professor declines to give the details of his discovery now, but says it is a definitive solution of the problem which occupied the minds of scientists for a century.

USEFUL INFORMATION.

Playing Cards.

The game of cards is of very ancient origin, and is supposed to have originated in Asia. The Chinese have 30 cards in a pack—three suits of nine cards each, and those independent cards which are superior to all others. They retain this style and game to the present day. The European cards and game probably came from Hindostan. The cards were called *tschu har-tas*, a word signifying four crowns or four kings. Cards were also used by the Arabs, when the game was connected with religious, necromantic or scientific associations.

Cards were introduced into Europe previous to the 13th century, probably by the Saracens. As first introduced, they were quite different from those in use at present. In shape they were square, and instead of suits of spades, clubs, hearts, and diamonds, their marks were rabbits, pinks, roses and flowers of columbine. The figured cards were very prettily devised, a queen riding on horseback with a rabbit beside her marked the queen of rabbits or of clubs. A rustic-looking man, grotesquely dressed, and standing in a strange attitude, with a pink beside him, signified the knave of pinks or diamonds.

Their first appearance in Europe seems to have been at Venice, where for a long time they were *painted*. In 1441, as the municipal records of that city show, the art of *painting* cards, which appears to have become quite an industry in Vienna, was seriously interfered with by the appearance of cards which were evidently *printed* from wooden blocks. This was probably the first work of the kind ever done outside of China.

The printing of cards was soon followed by similar devices on cloth for altar-pieces and images of various kinds. Printing from movable metallic types and the entire art of printing soon followed.

Soon after cards came into general use throughout Europe, so much time was spent with them and they led so universally to gambling that several of the European Governments prohibited their use. But the prohibition had no effect and their use became more and more popular, especially among the noblemen and in royal circles. It was probably about that time that the characters began to be changed. In the change the characters are supposed to have been intended for the four different classes of society. The hearts represented the clergy; spades (Italian *spada*, a sword), the nobility; diamonds, the citizens; and clubs, the serfs.

FISHING BY ELECTRICITY.—The idea of utilizing electric lights in fishing has now got beyond the experimental stage, not only in Europe, but in our own country, for we read that there are fishermen on the coast of Maine who are now fishing by electric lights. This is not a new departure, said a fisherman recently, but new ways of utilizing the lights have been discovered. The old way was to plunge an incandescent lamp into the water, the connection being made with some source of electricity on board the fishing vessel. When this was used in deep-sea fishing, it was found that the mains to the lamp often got foul of the fishing tackle or the cable of the vessel, thereby destroying its usefulness. A Frenchman has surmounted the difficulty by adopting a lamp worked by a primary battery, the whole of which can be thrown overboard and regained when the trip is ended. The battery consists of six Bunsen cells, in which, however, chromic acid is placed instead of nitric acid, formerly used. The cells are connected with a 12-volt Edison lamp. The success of the recent experiments presages the general adoption, by our coast fishermen, of this new discovery.

ARTIFICIAL COFFEE.—Of late artificial coffee-beans have been found in the European (German) market. They are made from roasted grain flour, with an addition of dextrine or some such body. There are two such establishments at Koln which furnish the necessary outfit, with formula, etc., for the manufacture of the beans. According to an original letter from one of these establishments in the possession of Dr. A. Stutzer, in Bonn, from 1000 to 1200 pounds of beans may be made in one day with the outfit, which the firm offers at a high price. The letter further predicts a golden future for the article, but advises that it be used for the adulteration of genuine coffee only in such countries where the laws are not very stringent, etc. These prospects must be very enticing to sophisticators, especially as the imitation is so perfect that only a very critical examination will serve to detect the adulteration. The artificial bean distinguishes itself from the genuine in being perfectly symmetrical and of the same size, and that the epidermal membrane is entirely wanting.—*Ex.*

THE FIRST USE OF WOOD FOR PAPER.—The discovery of the value of wood in paper-making is credited to Dr. H. H. Hill of this city. About 40 years ago the doctor visited the paper-mill at Vassalboro, and after looking over the machinery, suggested the feasibility of using wood, and asked why the manufacturers did not get a few bales of excelsior from Augusta, where it was made, and try the experiment of making paper from wood. "It can't be done," said the manufacturers, "Have not you as much gumption as the hornets, whose nests are made of wood paper?" asked the doctor. The result of the conversation was a letter, some time later, from the firm's wholesale agents in Boston asking what they were putting in their paper to make it so much better than it had been. It was the wood, then first used in this way.—*Kennebec (Me.) Journal.*

THE BROOKLYN BRIDGE.—Food often stimulates rather than satisfies the appetite. There can be no question that inventive genius continually suggests new wants. A New York contemporary says that a second Brooklyn bridge should be begun at once, and thinks it highly probable that as soon as it is completed a third bridge will be a necessity. The mayor of Brooklyn shares in the desire for additional means of communication with New York, nor is the wish unnatural if Brooklyn's rapid growth be taken into account. Since the beginning of the present bridge her population has doubled, and it is predicted that early in the next century it will equal the present population of New York. With three bridges connecting the two cities, the talk of consolidation would not appear visionary.

SOUND GRAINS OF SENSE.—It is rather singular how many persons there are who feel obliged to make noise while at work. Some of the noises are alleged singing, whistling—"for want of thought"—shuffling with the feet, and downright hurrahing. We have never observed that earnest, thoughtful men were great whistlers while at work or that they danced jigs. In an office we know of, several men work at drawing, and a perpetual blast of whistling, shouting, halloos, and uproar of various sorts issues from the fanlight during the day. It must be a pleasant place to work for those not riotously inclined. It sounds like a menagerie.—*Engineer.*

IMPROVEMENT IN PLASTERING.—An Eastern man has invented two kinds of plastering composition. That to be used for the first coat consists of sand, sawdust, plaster of Paris, slaked lime, sugar and carbonate of soda, while that for a second coat is made of cream tartar, pumice-stone, sugar, lime and plaster of Paris, each composition being compounded and applied in proportions and after a manner described. Both compositions have been patented.

A NEW EXPLOSIVE FROM MOLASSES.—A German patent has been granted to A. Doutrelpont for a process of preparing a new explosive, "petragit," from molasses. It is an oily nitro product, and is said to have three times the power of nitro-glycerine.

CIRCULAR APERTURES are most effective for discharging water, since they have less frictional surface for the same area.

GOOD HEALTH.

Health of the State.

The monthly circular of the State Board of Health for February has been received. From it we learn that mortality reports have been received from 67 localities with an estimated population of 665,700. The total number of deaths reported were 859, which gives an annual death rate of 15.48, which is an unusually small percentage for the season of the year, and indicates the absence of any epidemic disease upon the coast. Among diseases which have caused the greatest number of deaths are consumption, which is credited with 165; pneumonia, 92; heart diseases, 61; various diseases of the stomach, 38; diphtheria, 32; while cancer, the fourth on the list, is credited with 26. The large death rate from this disease is no doubt largely due to the persistent use of the knife instead of constitutional treatment. Bronchitis was fatal in 22 instances. All the deaths from this malady, with but one exception, occurred in the coast counties.

But four deaths are noted from cholera infantum; but as spring advances, a large increase from this disease is expected. It is very properly stated that when mothers become more familiar with household hygiene, we may hope to see this affection disappear from our list of prevailing diseases.

In cases of diphtheria the importance of thorough isolation is strongly urged. It should be borne in mind that this disease is almost as contagious as smallpox and twice or three times as fatal. Too much care cannot be taken in confining cases within as narrow a limit as possible.

TREATMENT OF DIPHTHERIA.—Much care and promptness is necessary in the treatment of diphtheria. A writer in *Science News* says: The local treatment of diphtheria by spray of solution of sulphuret of calcium is recommended by Dr. George E. Hubbard, New York. The solution is prepared as follows: Take of lime, 1 part; sulphur, 2 parts; water, 20 parts. Slake the lime with some of the water, then add the remainder and the sulphur. Boil to 12 parts and filter. Under the use of this solution, in spray, even sparingly applied, the diphtheretic patches undergo a change in a few hours. The temperature soon subsides, and a general improvement in the condition soon follows. In some cases the patches disappear entirely in a day. If the false membrane has developed rapidly before the physician has seen the patient, this spray will even then be effectual in arresting systemic poisoning, and soon the tough membrane will become detached. Do not, by any means, allow the patient to swallow any portion of the false membrane. By gentle manipulations it can be removed without causing any irritation. In cases of very young children it may be best to add a little water to the solution, at first, until we are satisfied that it does not irritate the tender mucus membrane. The doctor also thoroughly fumigates the apartments with sulphur, and administers such medicine as may be indicated. The principal thing to do is to destroy the disease germs as early as possible, and he believes the solution under consideration does much toward preventing constitutional infection as it is taken into the patient's stomach. Its stimulative, laxative, and somewhat diuretic action are quite marked.

ARTIFICIAL LUNGS TO RESTORE LIFE.—An object of great curiosity in Bridgeport, Conn., is a rabbit which Prof. George Poe, a relative of the late Edgar Allan Poe, has drowned 11 times and then brought back to life. The professor has invented an artificial pair of lungs, which he uses to restore life by drowning or asphyxiating. To demonstrate its usefulness he submerges his rabbit in water in the presence of witnesses, and holds it there for ten minutes. The rabbit has also been smothered with the fumes of burning charcoal, until all signs of life have been extinct. A mirror held at the mouth and nose showed no vapor, neither was there any heart action. Prof. Poe then attached his patent bellows covering over the mouth and forced oxygen into the lungs. The returning suction of the pumps drew out the deadly gases, and thus an artificial respiration produced a muscular expansion and contraction of the lungs of the subject until life was restored. Prof. Poe claims that he can drown and restore human beings as well as rabbits. He will not divulge the secret of compounding or the quantities of gases used. He thinks his artificial lungs will become generally adopted by fire departments and hospitals through the country. The rabbit after having gone through with these ordeals eight or ten times in the presence of witnesses, was quite well a few days since, according to the New York *World*, and jumping around the dooryard in a very lively manner.

THAT ACHE IN THE BACK.—An Albany physician, says a cotemporary, declares that Americans suffer more generally from Bright's disease and nervous disease than any other people, and he says that the reason is that Americans sit down so persistently at their work. He says: "Americans are the greatest sitters I ever knew. While Englishmen, Germans and Frenchmen walk and exercise, an American business man will go to his office, take his seat in his chair and sit there all day without giving any relief to the tension of the muscles of the back. The result is that these muscles surrounding the kidneys become soft and flabby. They lose their vitality. The kidneys themselves soon become weak and debilitated. If Americans would exercise more, if they would stand at their desks rather than sit, we would hear less of Bright's disease. I knew of a New York man who had suffered for some years from nervous prostration until it was recommended to him that he have a desk at which he could stand to do his work. Within a year he was one of the healthiest men you ever saw. His dyspepsia and kidney trouble had disappeared, and he had an appetite like a paver."

HOW TO HANDLE WASPS AND BEES WITHOUT HARM.—W. L. Wilder, in *Science*, says: "It is a fact not generally known that if one holds his breath, wasps, bees and hornets can be handled with impunity. The skin becomes stingproof, and, holding the insect by the feet, and giving her full liberty of action, you can see her drive her weapon against the impenetrable surface with a force that lifts her body with every stroke, but let the smallest quantity of air escape from the lungs and the sting will penetrate at once. I have never seen an exception to this in 25 years' observation. I have taught young ladies with very delicate hands to astonish their friends by the performance of this feat, and I saw one so severely stung as to require the services of a physician through laughing at a witty remark of her sister, forgetting that laughing required breath. For a theory in explanation I am led to believe that holding the breath partially closes the pores of the skin. My experiments in that direction have not been exact enough to be of any scientific value, but I am satisfied that it very sensibly affects the amount of insensible perspiration."

A NEW REMEDY FOR SKIN DISEASES, says the *Hospital*, is a continual bath, the patient eating, drinking and sleeping there until cured. One patient has been kept in such a bath for 385 days. He is tied up always at night to prevent him from slipping so as to drown. The palms and soles become much shriveled, but the rest of the skin is unchanged. The water is kept at 98 degrees.

THE DOCTORS DISAGREE.—It is reported that a New York physician, feeling "out of sorts," consulted five of his medical brethren in turn to learn what ailed him. Each one gave a different opinion of his case and recommended different modes of treatment. He believes they were all wrong.

ENGINEERING NOTES.

A NEW MODE FOR PROJECTILES.—A correspondent of the *Manufacturer and Builder* proposes to supplement the force of powder in discharging projectiles by the centrifugal action of the gun. He says: Allow me to suggest that by means of both forces (*i. e.*, explosive and centrifugal) combined, double the distance that either can obtain separately may be obtained. To do this with accuracy of fire, I would suggest that there should be attached to the trigger of the gun a long coil of wire of just exactly such a length that, when the gun, after being loaded, should be made to revolve on its trunnions by means of steam power, until such centrifugal force had been obtained of itself to carry the projectile five miles, the coil of wire having been unwound, would pull the trigger, and the projectile would leave the mouth of the cannon with a double momentum that would carry it double the distance—say five miles for each. Of course the length of the wire would have to be accurately gauged to insure accuracy of fire, or else the consequences might be prejudicial.

THE MANCHESTER SHIP CANAL.—The progress which has been made in the construction of this canal since the reorganization early in 1887, following the futile attempt to raise the necessary capital through the house of Rothschild, is highly satisfactory to the friends of the enterprise. The entire contract is let to Mr. Walker, who has already completed over one-quarter of the entire excavation called for, besides which a good deal of the retaining wall separating the canal from the estuary of the Mersey is in a forward state and some of the locks are started. One of the most serious engineering works to be overcome is the carrying of the Bindley canal over the ship canal. The crossing section of the canal will be carried in a large iron trunk, which can be swung out of the way when vessels are passing below in the ship canal. This will be quite a novel piece of engineering, and it is made necessary in consequence of the lack of water to lock up and down the smaller canal.

MEXICO will, the *Mexican Financier* holds, profit much by the construction of the Nicaragua ship canal, as it will enable vessels to sail all the way from Matamoras to Guaymas. While the canal can be used for purposes of naval defense, our contemporary does not think that this should alarm Mexico, "for the dangers of armed conflict with her northern neighbors grow less and less every day." The Nicaragua route is praised as being cheaper and healthier than the Panama. Good winds can at all seasons of the year be relied on by vessels bound for Brito, at the Pacific terminus of the Panama route, while owing to the calms, there are many months during which Panama can only be reached by steamers.

TURNING A LARGE RIVER FROM ITS COURSE.—A company has been formed in France, headed by a well-known Alsatian manufacturer, for the purpose of diverting the Guiers river to St. Christophe, where a fall of 200 meters would be thus obtained, representing a force of 4000-horse power, which would be utilized in developing electricity for the production of aluminium by a new process from the clay found in the district. It is asserted that by means of the process in question, aluminium, which is at present so costly, can be produced at a price that will very little exceed that of the cheapest metals.

FLOWING OF WATER IN PIPES.—A cylindrical pipe, flowing full, discharges less than the same pipe when only filled through a segment whose arc is 281 deg. 30 min. by 2.5 per cent, while the velocity is less by 9.5 per cent, the hydraulic inclination being the same. The full section discharges less, and also with less velocity, in other forms of pipes as well as in cylindrical. The scouring power of circular pipes flowing full is therefore less by nearly 10 per cent than that of the same pipes filled through an arc of 281 deg. 30 min.—a new element to be considered in the arguments for and against circular pipe sewers.

WHAT BECAME OF THE MONEY?—It is estimated that of the sixty millions sterling sunk in the Panama canal bubble, ten per cent has gone to French bankers, five per cent has been paid in bribes to the French press, ten per cent has gone to the inner members of the canal ring, who have had the giving out of the contracts, and most of the balance has gone to enrich the contractors. It is estimated that less than one-half of the work has even now been done.

ELEVATOR INSPECTOR.—Supervisor Bush has introduced an order providing for the appointment of an inspector of elevators in this city and county and the periodical inspection of elevators. It was passed to print and referred to the Building Committee.

THE TEHUANTEPEC SHIP RAILWAY.—A recent cable dispatch says that a party of English engineers are about to begin the location of the route, and that the financial arrangements are completed.

LONG RAILROAD TUNNELS.—The Mont St. Gothard tunnel is 9½ miles long; the Mont Cenis tunnel, 7½; and the Hoosac tunnel 4¾ miles in length.

Passing Events.

The burning of the lower smelter of the Anaconda works, Montana, is a very serious affair, throwing out of employment as it does so many men and involving so large a pecuniary loss directly. The new works handled about half the output of the mines.

The shipment of silver bars from Napa county, this State, noted in our "Mining Summary," shows that silver mines are possible in our Coast Range. The gold mines at Los Burros, Monterey county, prove also that this range contains that metal in paying quantities.

Judging from recent news from Leadville, the leasing system has not worked well in all cases, and will be restricted in the future. Irresponsible parties have done injury to mining properties working under this system.

The returning miners from the Lower California gold mines do not bring back very flattering accounts of the new fields. There is gold there, but not in so wide a region as was hoped for. The Mexicans seem to make money, but Americans do not do so well.

The hydraulic miners have issued a circular to owners of gravel mines, which we publish elsewhere in this number of the PRESS.

The news from Paris respecting the copper syndicate is of great interest to copper miners in this country. While this syndicate has worked hardships to consumers all over the world, it has benefited the owners of copper mines by furnishing a steady market at good prices. A fall in the price of copper to the old rates will close down a number of mines on the Pacific Coast and elsewhere.

The Copper Situation.

The event the past week in the copper market has been the failure of the Societe des Metaux of Paris and the incorporation of a new Comptoir d'Escompte with a capital of 40,000,000 francs, one-half of the shares being reserved for shareholders in the old company, which will be wound up. This movement, no doubt, will lead, if it has not already done so, to the formation of a copper syndicate, based on the proposition made by the old syndicate, which, if it becomes an accomplished fact, will put the copper industry upon a more substantial footing, and, at the same time, keep prices down to such figures as not to restrict the consumption, but rather to its encouragement.

The proposition, as we understand it, made by the old syndicate to the American copper-mining companies was to extend the existing or three years' contracts 12 years, making them to run 14 years from last October. It is asserted that with this extension granted, English capitalists could be drawn into the enterprise, which would make it impregnable so far as finances would be concerned. The American companies hung back from entering into such long-termed contracts, but were rather inclined to the formation of a bank in which they would be represented by four directors, the full Board of Directors having the power, from time to time, to regulate prices for copper and also the amount of production. Pending negotiations to settle amicably all differences, the load of copper became unmanageable for the syndicate and its backer, the Comptoir d'Escompte. The situation was made still more trying by the Russian Government withdrawing its deposit of 25,000,000 francs from the Comptoir d'Escompte, followed by the suicide of a leading director of the bank, which precipitated a run on the institution. Events in Paris followed in quick succession, but no serious panic was produced, owing to the Bank of France and a number of leading bankers coming to the assistance of the Comptoir d'Escompte, enabling it to withstand a run, and allowing time to right the affairs of the bank, the syndicate and all in interest.

As we understand it, the American copper companies received letters of credit on such banking institutions as the Seligmans, Belmont & Co., Kidder, Peabody & Co., Brown Bros., Ladenburg, Thalmann & Co., Muller, Schall & Co., and others, for sums equivalent to the purchase price for the output of the guaranteed figure. Some of these guarantees were for only one year's product, while others, again, were for the full length of time, three years. A leading authority states that the American mining companies delivered the copper to the agents of the syndicate in this country, but drew only against their credits to the extent of those amounts of copper which were not sold to consumers in the United States and Canada. The result has been that many of the companies have drawn only a small part of the sums secured to them by credits.

The question as to the immediate future of the metal is being raised, which in the light of the above and also owing to the fact that the stock of the speculators is hypothecated to strong parties, is altogether unnecessary. It is not at all likely that the institutions and private capitalists having money advanced on copper will throw their securities on the market, but rather they will hold so as to work it off to the best possible advantage, even if the syndicate now reported to be forming does not take it off their hands.

In connection with the above, it may be of interest to state that Henry R. Merten & Co. make the stock of copper in England and France, and afloat thereto from Chili and Australia, as follows: February 28, 1889, 218,140 tons; January 31, 1889, 109,528 tons; December 31, 1888, 101,105 tons; February 29, 1888, 52,593 tons; February 28, 1887, 59,546 tons; January 1, 1888, the visible supply in England, France and the United States was 54,098 tons, and on December 31, 1888, 151,995 tons.

Shasta County Mines.

Mr. George Johnson, from the Little Nellie mine, near Iron Mountain, Shasta county, favored us with a call a few days since. The mine is owned by B. N. Bugbee of Sacramento, and arrangements are now being made to put a mill upon it. They are running a tunnel to cut the ledge about 350 feet from the surface. The tunnel is run in about 350 feet, and will go 400 feet further to cut the pay shoot. The old, or upper tunnel, is 200 feet above the new one. There is rock enough above the upper tunnel to keep a mill running a year or two, and there are 250 tons of auriferous ore on the dump. The best of the ore has already been selected and shipped to Selby & Co.

About three weeks ago another and parallel ledge was struck, known as the Adeline; so far as they have gone it shows a pay shoot of about 350 feet. A prospecting tunnel 70 feet long has been run, and an eight-inch ledge of rich ore is the result. Some of the rock runs as high as $400 in gold per ton.

There are three other ledges connected with the mine—the Little Nellie No. 2, the Double E and the Julia. A fine water-power is obtained from Boulder creek, which empties into Spring creek, this in turn emptying into the Sacramento river.

Mr. Johnson states that the Iron Mountain mine is now doing very well under the superintendency of James Sallee, one of the owners. They are running 20 stamps, with pans and settlers, and although the ore is considered rebellious, they claim to work it up to 90 and 95 per cent. They are delivering the ore in the mill for 37½ cents per ton. The ledge or deposit is about 300 feet wide. The sulphurets are plentiful, and they are now moving the furnace to a higher level, 60 or 70 feet above the creek, so as to handle them more readily. They have on hand now about 500 tons of sulphurets, and as soon as the furnaces are moved will roast and work them.

The work is paying better than it ever did before. Drifts and tunnels have been run to prospect the vein, but it is being worked at present like a quarry, so large is the deposit. The cave last fall blocked operations, but the mill has been running since February 15th.

Steam-Launch Building.

Of late quite a number of steam launches have been built in this city for use in this bay and the rivers and harbors of Alaska. The launch Ida, recently built for the Kodiak Packing Co., Alaska, by the Atlas Iron Works, has some peculiar features. Her dimensions are: Length, 36 feet; beam, 9 feet; depth, 5 feet. She is fitted with compound engines, with cylinders 6x10½ inches, with an 8-inch stroke. Her propeller is 3 feet in diameter, with a 5-foot pitch.

The peculiarity about the Ida is that a brass pipe projects from the port side of the vessel, abaft amidships, and extending along the side is connected with a series of 32 small metal tubes, each three feet in length, arranged vertically under the launch's counter, and looking like a gridiron. This acts as and takes the place of the condenser, usually used on a steamer. The steam from the boiler goes through the pipe to the tubes, is there condensed and the water flows back to the vessel's hold, where it is again pumped into the boiler. J. B. Jardine is the inventor of the system, and he says while a vessel of that size usually carries five tons of water and a condenser weighing about a ton, the Ida only carries half a ton of water, which is used over and over again. He says that a voyage could be made to China with two tons of water. Purser Smith of the Mariposa, who is a natural-born mechanic, made a critical examination of the "gridiron," and says that it is a most valuable invention, and would prove of great benefit to the numerous steam yachts in use down in Australia.

A vessel a size larger called the Frances M. Cutting, and on this same plan, will shortly be illustrated and described in detail in the PRESS. This is one of six now in course of construction at the Atlas Iron Works.

COL. GEO. H. MENDELL of the U. S. Corps of Engineers leaves this week for Europe, for the purpose of studying the methods of river and harbor improvement there, with a view to applying the information obtained for the benefit of the Columbia river.

Electric-Power for Mining Work.

(*Continued from page 201.*)

be utilized for operating the dynamos, but where such power is at a greater or less distance from mine or mill. Sometimes water-power is available on the other side of a mountain or hill, or further down the canyon or gulch. In such cases water-wheels may be connected with the dynamos, and the power thus generated be transmitted to the motors at the desired point.

In many instances of this kind the water-power itself would cost nothing, and the plant alone is necessary to utilize it. If the water-power is scarce, large wires must be used to save loss; but if there is a surplus of original power, smaller wires may be used at less than first cost.

There is nothing mysterious or doubtful about this power or its mode of application. A water-wheel or steam engine is connected to an electric dynamo, which on being revolved generates an electric current which passes over the wire to the electric motor at a distance, this motor in turn being revolved. This is connected by belt to the shafting of any machinery. There is a certain loss of power between the dynamo and motor, depending on the distance, size of wire, etc. There are governors on the water-wheel and the dynamo and motors, and the rate of speed can be regulated by ordinary appliances. Starting and stopping are done at will precisely as with an engine or other power.

The modern electric motors are, in most essential particulars, like dynamos; only they have opposite functions. A dynamo is an instrument to which power is applied to rotate its armature, and that power, which is mechanical energy, is thereby converted into electrical energy (electricity). An electric motor is a dynamo to which we apply electrical energy. Its armature rotates, and through a pulley attached thereto, power (mechanical energy) is obtained. These properties of dynamos and motors properly associated make them valuable as means of transmitting power in large or small quantities from places where produced to places where used, be the distance over which transmitted a few hundred feet or many miles.

The California Electric-Light Company, which put in the electric plant on the Comstock, have in this city both a lighting and power system on an extensive scale. They furnish power in different parts of the city and have no difficulty of any kind. They have recently sold a large plant to go to Oregon City, where there is a fine water-power, and this power will be utilized for both power and lighting in Portland, Oregon, 12 miles distant. In the latter city the power and light will be distributed in all directions wherever wanted.

The Pacific Power Company, in this city, which furnishes the Keith electric motors for running the presses and elevator pump in the MINING AND SCIENTIFIC PRESS offices, distributes its power to various industrial establishments within a limited area at present, but distributes 160-horse power to 31 different stations, in quantities of from one to 25-horse power. They are recovering up to 75 per cent of the steam-power delivered to the dynamos.

OUR ILLUSTRATIONS.—The illustrations of the underground electric station in the Chollar shaft, the Nevada mill, and the motor-room in this number of the PRESS were made direct from photographs without redrawing, being perfect photo-facsimiles. The only exception is in the case of the buckets on the Pelton-wheel in the cut of the underground station, which were exaggerated unduly in order to bring out the relation of wheel to the dynamo. The cuts will give a very good idea of the general arrangement of this wonderful plant, while the description gives all the details of interest.

OMINOUS.—It looks rather ominous for the new Lower California gold-fields when there is serious talk among the prospectors about lynching a correspondent of certain papers on the ground that they were induced to go to the mines by reason of his false reports as to the richness of the placers. It is stated that the correspondent in question had to take refuge with the Mexican soldiery.

GOLD DISCOVERIES within a few miles of Holbrook, A. T., have caused great excitement at that place. The mines are placers, and many people are going to the new fields.

Electrical Power on the Comstock.

Combination of Water-Wheel and Dynamo.

All difficulties seem now to have been overcome, and the electrical transmission of power at the Nevada mill is in successful operation. In no other place in the world are dynamos run and electrical energy generated at so great a depth beneath the earth's surface, 1630 feet.

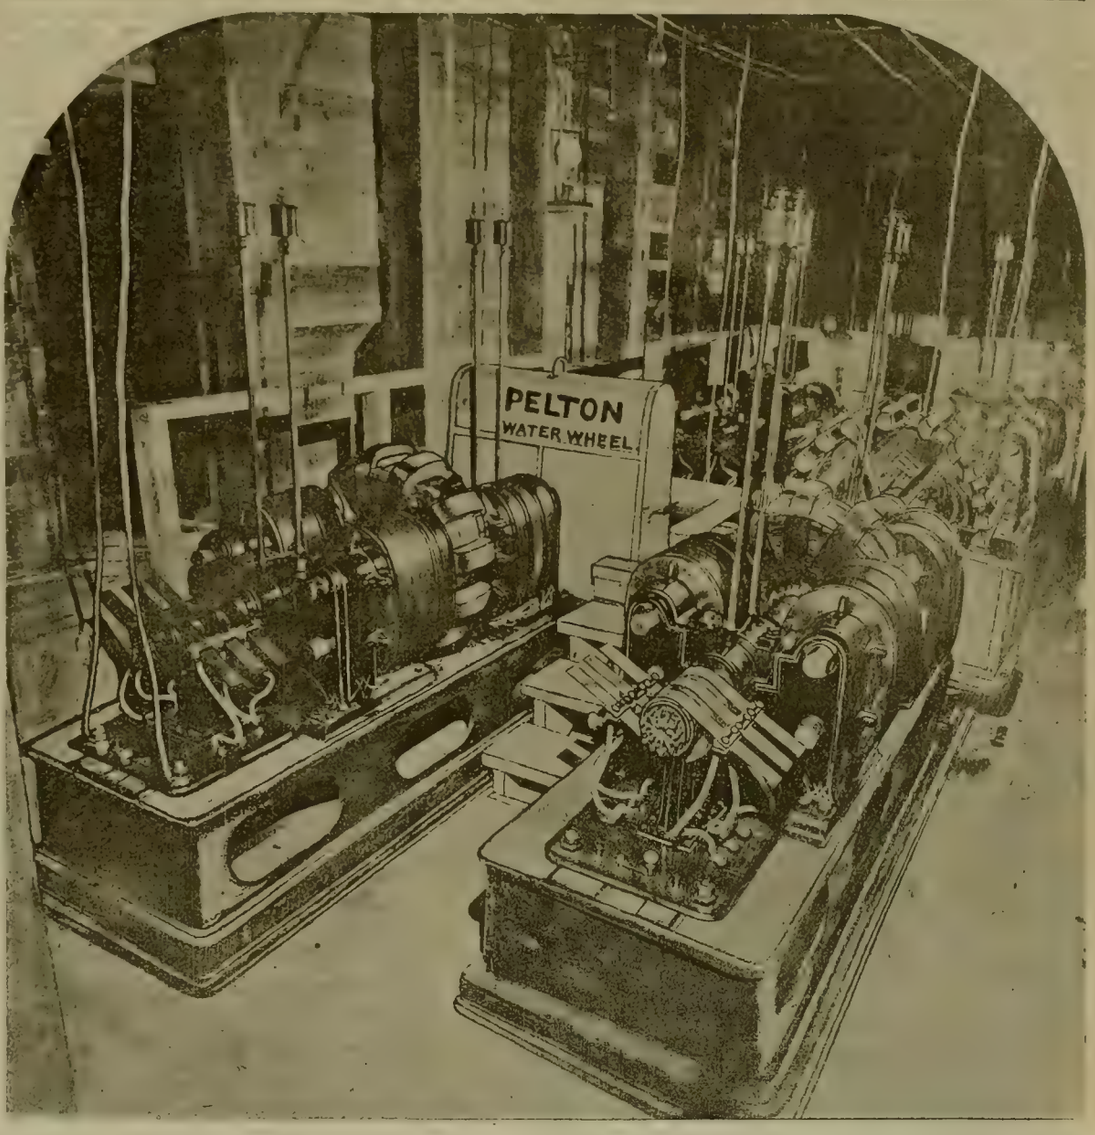
There were obstacles to be surmounted in putting in and successfully operating an electrical plant so far down in the bowels of the mother earth. Some of these could not be foreseen, and could only be remedied after the generators were set up and put in motion for a test run.

That which gave the most trouble and caused the greatest delay was that it was found necessary to take off and wrap anew the coils of the greater part of the bobbins of the armatures—a very great task. All parts of the dynamos were perfectly dry when taken into the mine, and it was naturally supposed would so remain, as there is not a drop of water in the rock in which the chamber that contains the apparatus was excavated. The air in this chamber is, however, very warm and contains by actual measurement 78 per cent of moisture. This being the case, any piece of cold metal which is taken into it—as a crowbar, axe or hammer—begins to "sweat," as the miners say. The cold metal condenses the moisture of the atmosphere and in a short time becomes quite wet. It was this moisture that collected in the coil of the dynamos wherever the atmosphere penetrated. Had this trouble been foreseen, the dynamos might have been so heated that when landed in the chamber their temperature would still have been above that of the atmosphere of the place. One would have supposed that the heat of the machines would have driven off this moisture, and it would have done so but for the fact that they were in this damp atmosphere for six weeks before being started, but it seems that when it had once taken up its residence in the coils, it stubbornly held possession, and would not be driven out by any ordinary means.

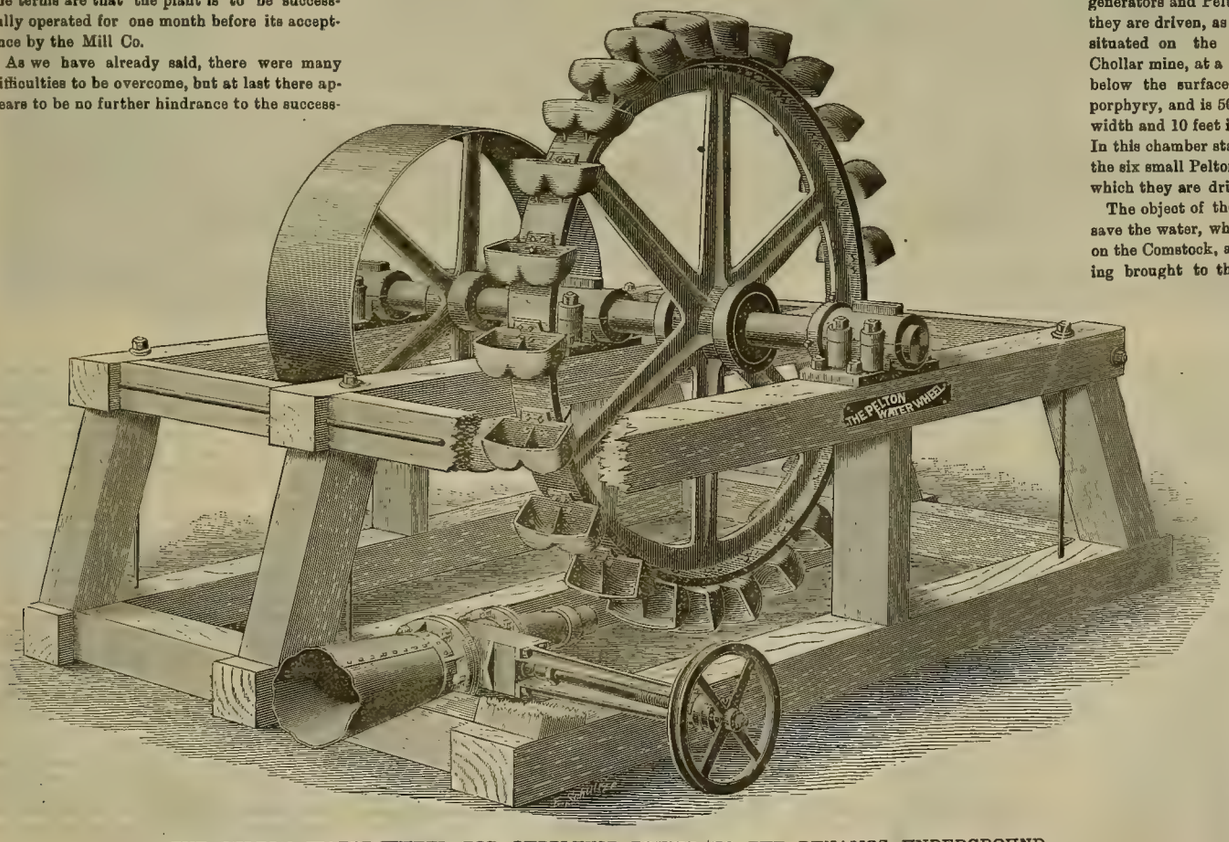
The motors that were in the power-house above ground, and not subjected to dampness, have not given the slightest particle of trouble, but worked from the first as if they had been doing it for years.

The Nevada Mill Co. contracted with the California Electric-Light Company George H. Roe, Secretary and Manager, for the plant. They are general agents for all the Brush apparatus—the kind here in use—and the terms are that the plant is to be successfully operated for one month before its acceptance by the Mill Co.

As we have already said, there were many difficulties to be overcome, but at last there appears to be no further hindrance to the successful operation of both generators and motors. The subterranean chamber in which stand the generators and Pelton water-wheels by which they are driven, as shown in the engraving, is situated on the Sutro-tunnel level of the Chollar mine, at a vertical depth of 1630 feet below the surface. It is excavated in solid porphyry, and is 50 feet in length by 25 feet in width and 10 feet in hight, clear of all timbers. In this chamber stand six Brush generators and the six small Pelton water-wheels, by means of which they are driven.



THE UNDERGROUND STATION, SHOWING DYNAMOS AND WATER-WHEELS.



THE PELTON WATER-WHEEL FOR SUPPLYING POWER TO THE DYNAMOS UNDERGROUND.

The object of the electrical apparatus is to save the water, which is both scarce and dear on the Comstock, all in use for any purpose being brought to the lode from streams in the Sierra Nevada mountains, a distance of about 30 miles. By twice using the same water on the Pelton wheels, a very large saving may be made, with an efficient means of transmitting the power on the second Pelton wheel, or set of wheels. At the C. and C. shaft of the Consolidated California and Virginia mines, the power is transmitted by means of steel-wire cables. There the same water is used on four different wheels. It is first used on a wheel ten feet ten inches in diameter on the surface [the pressure being derived from a pipe that runs from a tank high on the side of Mt. Davidson] in the California Battery Mill. It is then caught up and conveyed through a pipe to the C. and C. shaft, about 100 feet distant. In chambers

cut in the side of the shaft are three other Pelton wheels the same size as that on the surface. These wheels are 500 feet apart, the last being at the level of the Sutro drain tunnel, and the same water which is used above drives them all, it being caught up as it falls from each wheel and brought to bear on the next below, under a vertical pressure of 500 feet. By means of steel wire cables, the power developed by all three of the wheels is brought to bear upon a main driving shaft, and at the surface over pulleys, on which run cables, which transmit the power brought up the shaft 1500 feet, a further distance of 1600 feet, to the California pan-mill—a total distance from the bottom wheel of 3100 feet.

At the Nevada mill the object is to do by means of electricity what is done at the California mill by use of cable. The Nevada mill contains 60 stamps, with the usual complement of pans, settlers and other apparatus. On the surface, in the mill, is a Pelton wheel 10 feet 10 inches in diameter. An iron pipe leads to this wheel from a tank on the side of the mountain, and the stream thrown from the nozzle into the buckets of the wheel is under a vertical pressure of 460 feet. The water that falls from this wheel flows to a tank, whence it is conveyed to the main shaft of the Chollar mine through two iron pipes, one 10 inches and the other 8 inches in diameter. These pipes descend the shaft and thence the incline, at the bottom of which a Y unites them to a single wrought-iron pipe 14 inches in diameter. Out of this large pipe-head, six six-inch pipes run to the nozzles of the six Pelton wheels.

The Pelton wheels are 40 inches in diameter, and made of phosphor bronze, weighing only 220 pounds. Each wheel is capable of developing 125 horse power, with a stream of water passing through a nozzle less than half an inch in diameter, or 750 horse power in all. The object of introducing the dynamos and motors is to convey the power to the surface to run the machinery of the mill; to do by means of electrical energy, passing through copper wires, what is being done at the C. & C. shaft by means of steel wire cables, running over a series of pulleys. It was thought that the power might be transmitted in this way more effectively than by means of cables.

At the Chollar mine, instead of using water on a series of wheels, that is along down the shaft or incline, the whole of the water is at once carried in pipes to the level of the Sutro drain tunnel. There the enormous pressure of this column of water, 1630 feet in vertical hight, is applied to the Pelton wheels.

As no water-wheel of any kind had ever before been subjected to a force so tremendous, there were not wanting those who predicted that the wheels would be stripped of their buckets and broken to pieces; but they ran as smoothly and quietly as though under a pressure of no more than 500 or 600 feet.

The electrical chamber is lighted up by 36 incandescent lamps; all is a blaze of light. Although there are several lamps in the incline, the effect upon first stepping in the chamber is at first blinding, and almost startling, so great is the glare of the light.

On entering this subterranean lightning factory, the attention of the visitor is at once attracted to the huge humming dynamos. In vain they peer about for the power that sets the big machines in motion. Not a single wheel, piston or other object that seems capable of imparting power is in sight. The dynamo appears to evolve its wonderful energy from its "inner consciousness." The rapid motion seems the effect of internal rage. At last, after being long inwardly puzzled, the observer is sure to ask, "What is it that gives the dynamos their fearful velocity?" The querist is then told, to his astonishment, that it is a little water-wheel inclosed in the thin and small sheet-iron box seen standing at the end of each dynamo. The box is so small that it appears to be merely the head piece of the big generator, which it is causing to spin around at a speed of 900 revolutions a minute.

When the casing is removed from the wheel, the observer is even more astonished at the simplicity of the little wheel he sees before him. He examines it for a moment, and then cries, "Why, any one might have invented it." The wheel and its little box appear so simple that the first thought of every one is that he could have made such a wheel himself if it had happened to come into his head. Just there is the point; it didn't happen to come into his head. The same thing is true of a thousand other wonderful inventions.

After his first glance at the wheel it is discovered that the buckets are not so simple in construction as he for a moment before thought them. He finds that in the center of each rises a wedge-shaped partition, and that the stream of water striking this is divided and sweeps out through the curved sides in such a way as to produce a reactionary effect, in addition to that of the impact. At the same time the water is so deflected as to escape contact with the next buckets, thus preventing what in a turbine wheel would be technically termed "back lash." Another surprise is the small amount of water retained in the upper part of the wheel, in fact nothing is seen there but a mere spray. By the peculiar shape of the buckets, all the water is at once thrown down and out of the way of the wheel. After having spent its force, it falls to the bottom perfectly inert.

There has never been any trouble at the Chollar with the Pelton wheels. The hight of the column of water pressing upon them being at all times the same, their motion is necessarily unvarying. All the experimenting has been with the apparatus for the electrical transmission of the power developed by the water-wheels. Indeed, by means of a governor which has been added, the Pelton wheels have been made to regulate the vagaries of the generators and motors. This is effected by increasing or diminishing the flow of water through the nozzles.

At present there is a great scarcity of water. The amount obtainable is only sufficient to run 40 of the 60 stamps of the mill, and this in addition to the power transmitted by two of the lower Peltons to two generators and motors. But 40 stamps, with the complement of amalgamators and concentrating apparatus, are now being run with about 120 inches of water, running it first over the wheel on the surface and then into the pipes and down the shaft to the lower wheels, as previously explained.

The transmitted power and that developed by the upper Pelton now unite and pull together on the main driving shaft without the least discord. For some time past the two powers have been running together thus harmoniously, ever since the putting on of proper governors.

Mr. F. E Smith, the electrical engineer in charge, states that three, four or all six of the generators and motors may now be put on if thought necessary, and will work as smoothly in connection with the water-wheel above as now do the two in operation. But sufficient water to drive more than 40 stamps is not at present obtainable.

Before the motors were started, it required about 300 miners' inches of water to run 40 stamps, with their complement of pans, settlers, etc., but since the motors were started 120 inches only are required to do the same work, making thereby a saving, as will be seen, of 180 inches, or 60 per cent of the amount formerly used, by the use of the transmitted power.

As regards the per cent of power transitted, in a test made January 11th, the Pelton wheel which drove the generators developed 110-horse power, while the motor in the mill delivered to its belt 72-horse power, giving a net delivery of 65½ per cent. The speed of the generators, which is 900 revolutions per minute, is now kept constant by means of a hydraulic governor designed by Mr. Devereux of Aspen, Colorado, but modified and improved by Mr. Smith and the Pelton Water-Wheel Co., so that it now works to perfection.

Each generator is provided with an ammemeter. From the generators insulated wires lead to a switch-board situated at the foot of the incline, where any generator can be put on any motor circuit with only a moment's interruption. From this switch-board the wires follow the pipe line up the incline shaft out through the short tunnel, and are carried to the motor-house of the mill, where they again enter ammemeters and voltmeters and then are connected with each of the six motors. Each motor is capable of developing about 75 horse power, making 450-horse power available at the mill.

The power developed is transmitted a distance of about 2800 feet. At one place in the shaft the wires pass through a regular shower bath of water for a short distance. The loss at this place is said not to be noticeable. The ammemeters show the amount of current being developed and transmitted, and the automatic hydraulic speed-indicator, invented by Mr. Smith, shows the speed and steadiness at all times at a glance. This is connected with the Pelton wheels.

It seems that electrical transmission of energy is now to prove as successful on the Comstock as at Aspen, Colorado, and in many other places. The effort has been to make the transmitted power pull evenly from the same driving shaft with power developed by a water-wheel on the spot. Upon the success of the plant on the Comstock much has depended, as, being the largest one of the kind in the world, great attention has been attracted to it.

THE NEVADA QUARTZ-MILL WHERE THE ELECTRICAL POWER IS UTILIZED.

VALUABLE BOOKS ON MINERALS AND MINING.

A PRACTICAL MANUAL OF MINERALS, MINES AND MINING; comprising suggestions as to the localities and associations of all the Useful Minerals; full descriptions of the most effective methods of both the qualitative and quantitative analyses of each of these minerals, and hints upon the various operations of mining, including Architecture and Construction. By Prof. H. S. Osborn, LL. D. Illustrated by 171 engravings. 8vo. 367 pages. Price.....$4 50

☞A descriptive circular giving the full contents of the above book sent free to any one who will send his address.

A TREATISE ON METALLIFEROUS MINERALS AND MINING. By D. C. Davies. With 148 illustrations. 12mo, 432 pages. Price..$5.00

MINE DRAINAGE. By Stephen Michell. 8vo, 277 engravings. Price.....$6.00

A TREATISE ON EARTHY AND OTHER MINERALS AND MINING. By D. C. Davies. With 76 engravings. 12mo. Price.....$5.00

THE PROSPECTOR'S HAND BOOK. A Guide for the Prospector and Traveler in search of Metal-bearing or other valuable Minerals. Illustrated. 12mo. Price.....$1.50

MINERALOGY SIMPLIFIED. Easy Methods of Identifying Minerals, including Ores, by means of the Blowpipe, by Flame Reactions, by the Spectroscope and by Humid Chemical Analysis, based on Von Kobell's Tables for the Determination of Minerals, etc. By Henri Erni, M. D. Illustrated 12mo. Price...$3.00

UNDERGROUND TREASURES; HOW AND WHERE TO FIND THEM. A Key for the Ready Determination of Minerals within the United States. By James Orton. Price.....$1 50

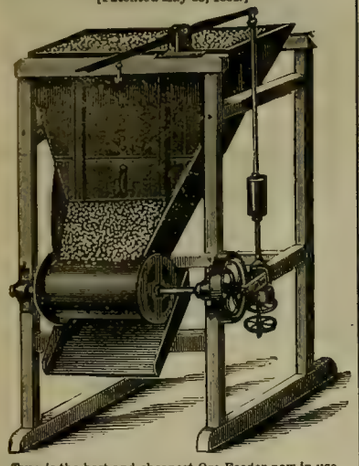
☞The above or any of our Books sent by mail, free of postage, at the publication prices, to any address in the world.

☞Our New and Revised Catalogue of Practical and Scientific Books, 84 pages, 8vo, and our other Catalogues, the whole covering every branch of Science applied to the Arts, sent free and free of postage to any one in any part of the world who will furnish his address.

HENRY CAREY BAIRD & CO.,
INDUSTRIAL PUBLISHERS, BOOKSELLERS AND IMPORTERS,
810 Walnut St., Philadelphia, Pa., U. S. A.

THE ROLLER ORE FEEDER

[Patented May 28, 1882.]



THIS is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,
Sole Manufacturers,
827 First Street. San Francisco, Cal.

Improved Miner's Candlestick.

Can be suspended from or stuck in timber. Point detachable and folds in so candlestick can be carried in the pocket. Guard automatically extinguishes candle when short, to prevent accidents. Patent rights for Pacific Coast for sale.

GABRIEL WERNTZ,
Placerville, El Dorado Co., Cal.

PARTNER WANTED.

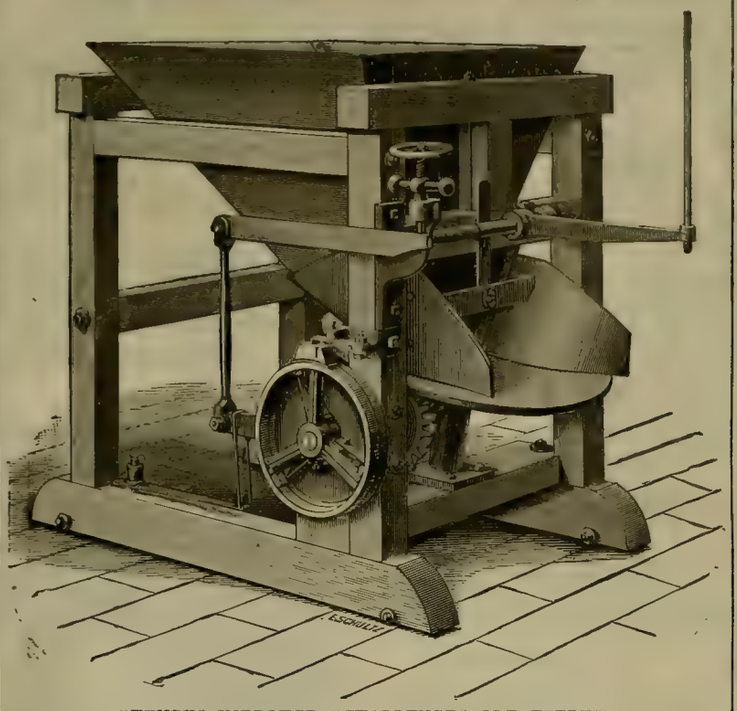
A first-class molder with $1000 or $2000 capital to take an interest in an iron foundry; good town, with immense agricultural country. Address

W. H. WILLISCRAFT,
Juniper, Arizona.

QUICKSILVER

For Sale in Lots to Suit by
PARROTT & CO.,
306 California St., San Francisco, Cal.

—THE—
JOSHUA HENDY MACHINE WORKS,
Nos. 39 to 51 FREMONT STREET, SAN FRANCISCO, CAL.



"HENDY" IMPROVED "CHALLENGE" ORE FEEDER.

The **best form of Feeder ever devised,** and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz.:

N. W. CROCKER, Supt. Bunker Hill Gold Mining Co., Amador City, Cal.
W. G. ROBERTS, Greenwood, El Dorado Co., Cal.
D. C. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.

WE ARE MANUFACTURERS OF THE
CHALL ENGE," "STANFORD," "TULLOCK," & "ROLLER" FEEDERS,
And will furnish descriptive Catalogues and quote prices upon application.

"RED FLAX CORD"

SQUARE FLAX PACKING,

Manufactured from strictly first-class Flax and pure lubricants. Superior to all others for Water and Steam. Packs with less friction and makes a tighter joint than any other packing made. ☞Imitations of inferior quality having been put upon the market, we have been compelled to adopt the above trade mark, and all of our packing will now have a RED CORD running through the center its entire length. See that you get it and take no other. Sold by all hardware dealers. Price, 50 cents per pound. **W. T. Y. SCHENCK,** Sole Manufacturer, 222 and 224 Market Street, San Francisco, Cal.

STEARNS M'F'G CO.,

29 & 31 Spear St., San Francisco, Cal.

—MANUFACTURERS OF—
HIGH-GRADE SAW MILL MACHINERY, ENGINES, STEEL BOILERS, Etc.
—IMPORTERS OF—
Munson's Leather Belting, Goodell & Waters' Woodworking Tools, Hill's Friction Clutches, Emerson's Saws, Emery Wheels, Tool and Knife Grinders, Ewart's Link Belting, L. & D. Wood Pulleys, Hoisting and Pile Driving Engines, Etc.

California Electrical Works

35 MARKET ST., S. F.
MANUFACTURERS OF AND DEALERS IN
Electrical Apparatus Supplies, Electrical Gas Lighting, Gold, Silver and Nickel Plating.
AGENTS FOR
Gamewell Fire Alarm Telegraph, Okonite Insulated Wires and Cables, Gassner Dry Batteries, etc., etc.

BACK FILES of the MINING AND SCIENTIFIC PRESS (unbound) can be had for $3 per volume of six months. Per year (two volumes) $5. Inserted in Dewey's patent binder, 50 cents additional per volume.

FOR SALE.

One 10x13 inch Clayton Belt Air Compressor.
Three 3-inch Sergeant Drills.
Three 5-ft. Double Screw Drifting Columns with Arms.
One 4-ft. Single Screw Stoping Bar.
One Set Sharpening Tools.
About 1500 pounds Drill Steel.
One 8½x13 ft. Air Receiver.
One Tustin Pulverizer, with new wearing parts, such as Rolls, Grates, etc.

The above are in first-class condition and will be sold cheap. For price apply to the
PAYMASTER MINING CO.,
Yuma, Arizona Territory.

—MANUFACTURERS OF—

Stationary and Compound Engines, Flour, Sugar, Saw and Quartz Mill Machinery.

AMALGAMATING MACHINES. CASTINGS AND FORGINGS Of Every Description

ALL WORK TESTED AND GUARANTEED.

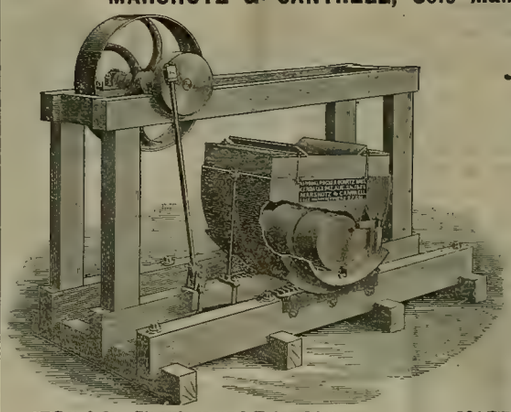
IMPROVED PORTABLE HOISTING ENGINES.

NATIONAL ROCKER QUARTZ MILL.

KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



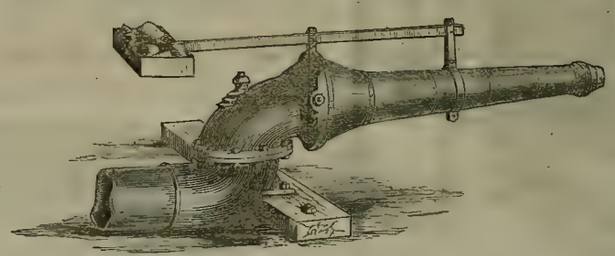
The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

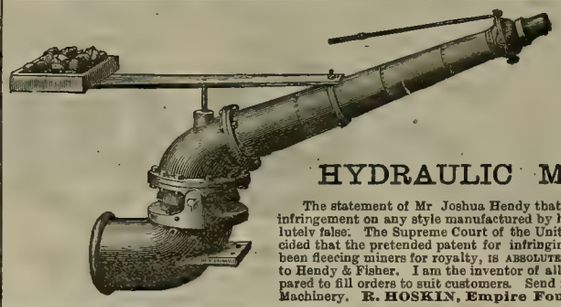
☞ Send for Circulars and Price List. MARSHUTZ & CANTRELL.

IMPROVED FORM OF HYDRAULIC GIANTS.



THE ABOVE CUT ILLUSTRATES THE IMPROVED FORM OF DOUBLE-JOINTED HYDRAULIC GIANTS which we manufacture. We guarantee purchasers of this form of Giants against all costs, expenses or damages which may arise from any adverse suits or actions at law. We are further prepared to furnish Single-Jointed Giants when required. Prices, discounts and Catalogues of our specialties of Hydraulic Mining Machinery sent on application.

JOSHUA HENDY MACHINE WORKS, 39 to 51 Fremont St., San Francisco.



HOSKIN'S IMPROVED ONE-JOINTED HYDRAULIC MACHINE.

The statement of Mr Joshua Hendy that ANY STYLE of machine is an infringement on any style manufactured by him, he knows to be absolutely false. The Supreme Court of the United States on March 19th decided that the pretended patent for infringing, which he has for years been fleecing miners for royalty, IS ABSOLUTELY VOID, with costs of suit to Hendy & Fisher. I am the inventor of all styles in use, and am prepared to fill orders to suit customers. Send for list of prices of Hydraulic Machinery. R. HOSKIN, Empire Foundry, Marysville, Cal.

MINERS ATTENTION!

SPRAGUE ELECTRIC RAILWAY AND MOTOR CO., OF NEW YORK.

LOW-GRADE ORES CAN BE PROFITABLY WORKED BY ELECTRIC TRANSMISSION OF POWER FROM DISTANT WATERFALLS.

Plants will, in many cases, pay for themselves in from 1 to 5 years by the saving produced by Electric Transmission compared with other systems.

Suspension and Surface Tramways, Hoists, Pumps, Drills, Stamp-mills, etc., operated by Electric Motors.

Electricity Triumphant.

The Largest Electrical Power Plant in the World.

The electrical plant for the transmission of power at the Chollar mine and Nevada mill, erected by the California Electric Light Co. of San Francisco, Cal., and under the supervision of Mr. F. E. Smith, the company's electrical engineer, is the largest electrical plant for the transmission of power on the globe.

The plant consists of six 120-horse power Brush compound-wound constant-current generators, situated on the 1600 level of the Chollar shaft.

The power used to operate them is water applied to Pelton wheels under a 1630-foot head, each generator being provided with a wheel of its own.

The water is conveyed to the generators through two lines of pipe—one 8-inch and the other 10-inch—which unite at the station. These pipes are carried down the shaft and incline to the station, whence the spent water is carried off through the Sutro tunnel to the Carson river.

The station is cut in solid rock and is 25 feet wide, 50 feet long and 12 feet high, and is lit by 7 incandescent lamps, which are supplied with current from the motor circuits. The average temperature of the station is about 68 degrees Fahrenheit.

The generators are each supplied with improved hydraulic governors, which control the speed perfectly. Each generator is also provided with a constant-registering hydraulic speed-indicator, which shows the least change in speed should it occur.

The terminals of each generator are connected to a switch-board situated at the entrance to the station, which is provided with ammeters and voltmeters, and arranged in such a manner that any generator can be connected to any motor circuit at a moment's notice. From this switch-board six circuits are run up the incline and shaft to the Nevada quartz-mill, which contains 60 stamps, with their complement of pans, settlers, agitators, rock-breakers, etc.

In this mill, on the surface, are placed six of the latest-improved Brush motors of 125-horse power each, connected by a belt to one line of shafting which is provided with belt-holders, thereby enabling an attendant to stop or start a motor at will. The motors are also provided with ammeters and voltmeters and speed indicators. Communication between the motor-house and station is by means of electric bells.

The electrical transmission of power has now been fully demonstrated on the Comstock to be not only feasible, but reliable and economical, and as the water supply in Virginia is limited, the economical use of it is a vital question. Sufficient has already been accomplished to prove that powerful electric generators could be placed on the Carson and Truckee rivers and their power transmitted to the Virginia City mills, thereby effecting such a saving in cost of milling expenses as to place the mining companies in a position to reduce low-grade ores at a profit.

Now that we can be assured of a steady stream of water in the Carson river by the building of a large reservoir, there will be sufficient power furnished not only to operate the mills in Virginia, but also for lighting purposes in the mines and for hoisting.

Mr. Smith has already set up hoisting plants in California, and he assures us that he feels perfectly confident of being able to put up a hoist plant that will raise all that any treble-decker on the Comstock will hold.

When Mr. Smith came to Virginia, he came under the impression of having to put up a long-distance transmission plant, and he longs for the opportunity of proving to the world that the electrical transmission of energy is the cheapest form of transmission and for long distances the only feasible system.

Two dynamos now run 40 stamps during the day, in conjunction with the Pelton wheels, using 78 inches of water. If there was enough water, the full complement of the mill could be run with the electric plant alone and there would always be one motor to spare.

It is proper to state in this connection that but for the electric plant at the Nevada mill, the scarcity of water would force its shutting down, throwing many men out of employment.

This immense plant was not started under the most favorable circumstances, because of the unlooked-for circumstances encountered in underground work of this description. It was found necessary to alter the insulating material used in the generators in order to overcome the difficulties arising from the collection of moisture in the coils, and this difficulty has now been entirely overcome and the generators are working to perfection.

Another cause for delay was the inability to obtain a first-class water-wheel governor that would perfectly control the Pelton wheels while working under an immense pressure, but after a great deal of experimenting with governors, a very simple device was found which works to perfection.

Having successfully overcome all the obstacles encountered in underground work of this description, Mr. Smith feels confident that in future there will be no cause for delay in starting any other plant of this kind.—*Virginia (Nev.) Enterprise.*

The Pelton Water-Wheel.

On another page of this issue is given a detailed description of the electrical plant now running in the Chollar shaft on the Comstock lode.

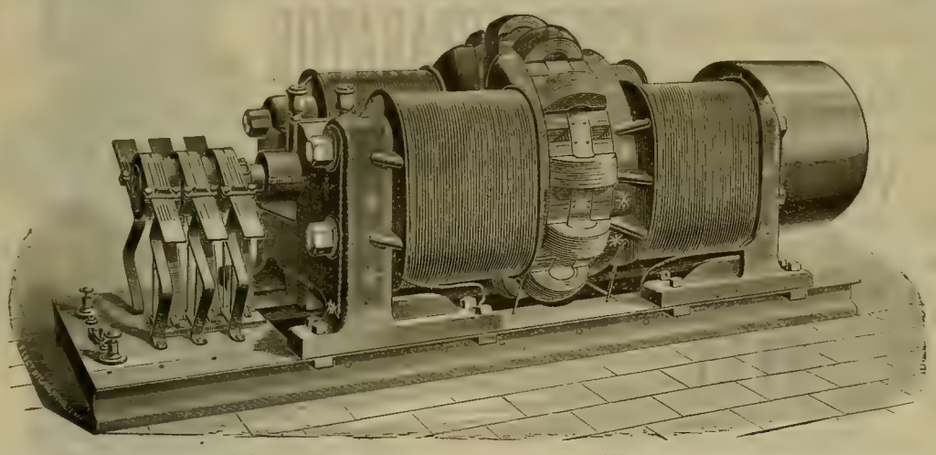
We desire to call attention to the fact that the cut (p. 209) showing dynamos and Pelton wheels in the underground chamber greatly exaggerate the wheels as regards size, as also the buckets on the face of the wheels. The wheels are only 40 inches in diameter and the buckets only 2½ inches in width. The illustration herewith shows a standard six-foot wheel as ordinarily set in frame ready for use, excepting the cover. This reduced about one-half would give a correct idea of the wheel-running dynamos referred to.

In this instance the wheels are attached to the dynamo shafts direct, thus dispensing with all intermediate gearing, and made of a size to give the proper speed to the dynamos, 900 revolutions. They are calculated, however, to stand the enormous speed the velocity of the water would give them running without load, which would be 1800 revolutions, giving the periphery of the wheel a speed of 18,864 feet per minute, the water flowing from the nozzle with a velocity of 19,260 feet per minute. It may be here stated that under this tremendous pressure, there is no loss of efficiency in the wheels, the average being from 88 to 90 per cent.

Our readers are so familiar with the Pelton wheel that a detailed description is unnecessary. No one at all acquainted with the industrial progress of the Pacific Coast during the past few years in the department of mining and manufacturing can fail to be impressed with the important part this wheel has borne in the rapid development of these varied interests. A fine engraving of the wheel is given on page 209.

The Pelton wheel is the product of California genius, and as such is our especial pride. It was evolved out of the most pressing necessity, a condition of things that nowhere else existed, and to which no other form of wheel was adapted. The wonderful success that has attended its operation on this coast, as well as in all other localities where it has been introduced, marks a new era in the use of water as a power.

On account of the large volume of water required for turbine wheels, and the limited head under which they can be run, comparatively few of the great number of water powers the country affords have been utilized. The high efficiency of the Pelton wheels admits of great results being accomplished from a small amount of water, especially when a considerable head can be obtained. This is in the majority of cases much more easily accomplished, from the fact that the reduced quantity of water admits of being carried by pipe a considerable distance at comparatively small cost. Thus the old forms of water motors are giving place to the new, with great gain in the matter of economy as well as with a much wider range of application.



BRUSH DYNAMO-ELECTRIC GENERATOR FOR CONSTANT CURRENT.

California has given the world not only its wealth of minerals, but what is of equal value, the wealth of its resources in mechanical achievements, which for boldness of conception, originality of design and adaptability to existing conditions, bear favorable comparison with the products of any of the older States.

Water has come to be recognized as one of the most potent of all natural forces, and the appliances for its high utilization are enlisting interest and attracting attention now as never before all over the world.

The Generators and Motors.

The electrical plant on the Comstock at the Chollar mine and Nevada mill is on the Brush system. The Brush electric motor is a perfected machine of which many thousands are in use, taking the place of small engines and other power devices. The motor is *not* an electric-light dynamo run as an electric motor, but specially adapted for the work it is to do. The motors are strong, compact and built to withstand a great strain. The mechanical details have been thoroughly considered.

The generators return a very high percentage of driving-power, and are built in all sizes. The plant on the Comstock consists of six 120-horse-power Brush compound-wound, constant-current generators, each generator having its separate Pelton wheel for power. Special improved hydraulic governors control the speed. Engravings in detail of both the dynamo and generator are given in this number of the MINING AND SCIENTIFIC PRESS, and the larger engravings show them in position.

The result of the application of this power on the Comstock has been so successful that it will doubtless be used in many other places on this coast where circumstances admit. The adaptability of the system for power and lighting purposes in mining has been elsewhere proven; but this on the Comstock is the largest electrical-power plant in the world.

The Fox Platform and Coupling.

The Nevada County Narrow-Gauge Railroad Company has recently, after an extended trial, adopted the Fox platform and coupler for its cars. The device is also being tried on another road in this State and will doubtless be adopted there also, as it has given great satisfaction. It is an improvement on the Miller in many ways. The cars can be readily uncoupled even when there is a strain on the bars, and this can be done when the cars are on a curve as well as when they are on a straight line of track.

The bumper comes flush with the platform and has an automatic lateral motion, adjusting itself to any curve. Close parallel connection is made between the platforms on a curve, the same as on straight track. A spring is placed at the back, so the edges are kept flush at all times.

The coupling is in shape much like the Miller, but connects and disconnects much more readily. By means of the ordinary lever on the platform a bolt is pulled back and the head then turns itself so as to release or catch automatically. This swinging or movable action of the head on the bar simplifies the whole action of coupling and uncoupling. A very slight pressure uncouples the cars even on a sharp curve.

The construction is such that by taking out a bolt another head may be put on to couple with the Jenny type of coupler. It will, in the ordinary form, couple to the Miller as well as to its own type.

A company has been formed in this city to manufacture this appliance. It is called the Fox Platform and Coupling Co. L. C. Parke is president, and the other directors are B. T. Lacy, Squire V. Mooney, W. B. Wilshire and F. A. Fox. Contracts for manufacturing have been made with the Pacific Rolling Mills. At the office of the company, 21 and 23 Fremont street, is a miniature track and cars, where the practical workings of the device may be examined. John F. Kidder, president and manager of the Nevada Co. R. R., says the invention has been placed on their passenger coaches and meets his approval in every respect, doing all that is claimed for it under the most trying circumstances, viz.: Coupling and uncoupling without any trouble on a 24° curve. He thinks it the best coupler he has ever seen, and will apply it on all the cars of the road, both passenger and freight.

At the Convention of Railroad State Commissioners at Washington this month, they urged upon the Interstate Commerce Commissioners to consider what could be done to prevent the loss of life and limb in coupling and uncoupling freight cars used in interstate commerce. At the close of the session, R. R. Commissioner Coffin of Iowa, now representing the Brotherhood of Brakemen, stated that in Iowa alone, in ten years, 2424 men were killed or maimed while using the old pin and link coupler and hand brake on freight cars. Last year there were 349 killed. On the 150,000 miles of railroad in this country over 6000 active, strong men were killed or maimed last year from these two causes alone.

This is a startling statement and it is time there was enforcement of some rules compelling the use of automatic couplers on freight as well as passenger cars. The Fox coupler works so much more easily than the Miller and overcomes the difficulty the Miller has in operating on curves, that it is very probable its use will rapidly spread as its merits become known. No time at all is lost in uncoupling, the withdrawal of the bolt by the lever allowing the head to swing instantly.

To the Miners of California.

The following circular addressed to the miners of this State being self-explanatory, it need only be added that the names thereunto attached, many being omitted, represent parties prominent in every branch of mining—vein, drift and hydraulic alike:

As is well known, numerous parties engaged in the business of mining in this State have been enjoined from working their mines by order of the courts. While the properties so restrained from being worked have thus far consisted mostly of hydraulic mines, they have included also those worked by drifting as well as by other methods more or less in use.

The reason assigned for closing these mines is that their tailings foul the water and so fill up the beds of the outletting streams as to injure the land lying along them and impede navigation. As no class of mines can be operated without contributing in some degree toward causing the injury complained of, it follows that all, vein and placer alike, are exposed to be closed by mandate of the courts. Such being the case, it behooves the miners everywhere to make common cause against this common danger, to which end they should lose no time in coming together and organizing for mutual protection.

There exists already an institution known as the "Miners' Association," formed originally for the above purpose, and which might now be availed of for carrying out the same, or a wholly new organization might be formed if deemed expedient; the object of this circular being to impress upon the miners the importance of taking early and efficient action in the premises.

In addition to the State organization above alluded to, with its headquarters in San Francisco, local associations should be gotten up in every mining county in the State, and which, while giving special attention to home matters, would act in concert with the central organization.

The Debris Commission provided for by Act of Congress is now in the field and actively engaged in the discharge of its duties, which consist in ascertaining whether or not any plan can be devised whereby the present conflict between the farmers and the miners can be adjusted and the mining industry be rehabilitated. The present is therefore an opportune moment for the miners to organize, and through united action aid the members of this Commission, as far as possible, in the hope that their report to Congress will be of such a character as will induce that body to appropriate means sufficient to carry out such plan for disposing of these tailings as the Commission may recommend.

MESSRS. FRENCH & LINFORTH, 35 Beale street, this city, are agents for the "Everlasting Whiffletree," something new in construction, the body being steel pipe tapering neatly toward the ends. They are durable, strong and light, and there is no danger of the trimming becoming loose, as is the case with wood. This firm is also agent for Gandy's American cotton belting, made of fine-grained cotton duck stitched in a peculiar way to insure an even surface and large gripping-power. This belting is specially adapted for heavy stamp-mill machinery. It runs straight, does not slip or harden, and is not affected by atmospheric changes. The same firm is also agent for Robert Mann & Sons' chopping axes; Thos. R. Mann & Co.'s Climax (all steel) axes and Robert Mann double-bit axes; J. Barton Smith Co.'s screw-tang files and rasps and their saws; Nashville Spoke & Handle Co.'s ax, pick and sledge-handles; Thos. Devlin & Co.'s malleable iron-pipe fittings and hardware, and several other things in the hardware line.

MR. C. H. AARON has resigned his position in the State Mining Bureau, where he has been engaged for some little time.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

A. F. JEWETT—Tulare Co.
F. B. LOGAN—Southern California.
H. G. PARSONS—Southern California.
GEO WILSON—Sacramento Co.
J. C. HOAG—San Francisco.
CHAS. F. BLACKBURN—Idaho.
FRANK S. CHAPIN—Colusa Co.
MRS. E. J STEPHENS—Sierra Co.
R G. HUSTON—Montana.
E H. SCHAEFFLE—Calaveras and Tuolumne Cos.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Mining Share Market.

Speculation in Comstock stocks the past week was tame, as if the pool is quietly operating for a gradual sinking in prices to keep the short element from filling, and at the same time take in all the outside stocks offering. The nature of the work going on in several, if not in all, the mines also gives color to the above. Take as an example Best and Belcher. By those who should know whereof they speak, it is asserted that in running the four crosscuts as each came to the ledge, work was discontinued. This, no doubt, if the case, was done for the pool to find out the extent of the ledge and its richness, and at the same time make small deals in that of other sympathetic stocks. The news this week from the mines is as follows; A still further improvement on the 400 level of Hale and Norcross running toward Savage, an improvement on the crosscut in Savage running to intersect the ledge from Hale and Norcross, and quite a decided improvement in the Ophir winze and upraise. An important improvement is reported on the Yellow Jacket 300 level near the Challenge line. The ore in Crown Point is reported as assaying about $36 per ton. There is no official statement as to the assay of the ore of this mine, and as for that of several other mines, notwithstanding the law states that must be done weekly. Advices from Virginia City are confirmatory of large deposits of snow in the mountains. The latest advices of it being reported by telegraph state that in the canyons and gulches several feet of snow are piled up, while on a level the snow is about six feet deep. This assures water for milling purposes well into August. The question is naturally asked, with an abundance of water, why the 60 stamps in the Nevada mill are not dropping, and also why the California pan-mill is not started up? In the outside stocks—Tuscaroras, Bodies and Quijotoas—trading the past week was, like in the Comstocks, decidedly tame, although toward the close more was doing, with a slight advance in the last two. The news from the mines in the three districts is of the same tenor as heretofore published.

At the Chollar annual election both secretary's and superintendent's reports were read, which did not differ materially from former reports.

Ore shipments from Comstock mines last week aggregated 6393 tons, and included the following: Con. Cal. and Virginia, 2550 tons; assay value, $34.90; Savage, 530 tons; assay value, $20.49; Hale and Norcross, 900; Confidence and Challenge, 807 tons; assay value, $26.68; Crown Point, 888 tons; Overman, 268 tons; Justice and Alta, 450 tons. The bullion yield of the above ore was about $135,000.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Con. California and Virginia, March 16, $75,000: Hale and Norcross, 16, $78,098; Savage (for February), $29,066; Justice, 19, $2625; Overman, 6, $9171; Hanauer, 12, $5900; 13, $2000; 14, $3300; 15, $3300; 16, $6200; Mt. Diablo, 18, $7443.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

ASSESSMENT NOTICE.

Gray Eagle Mining Company.—Location of principal place of business San Francisco, California. Location of works, Placer County, California.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 19th day of March 1889, an assessment, No. 12, of Five Cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Room 9, No. 327 Pine Street, San Francisco, California.

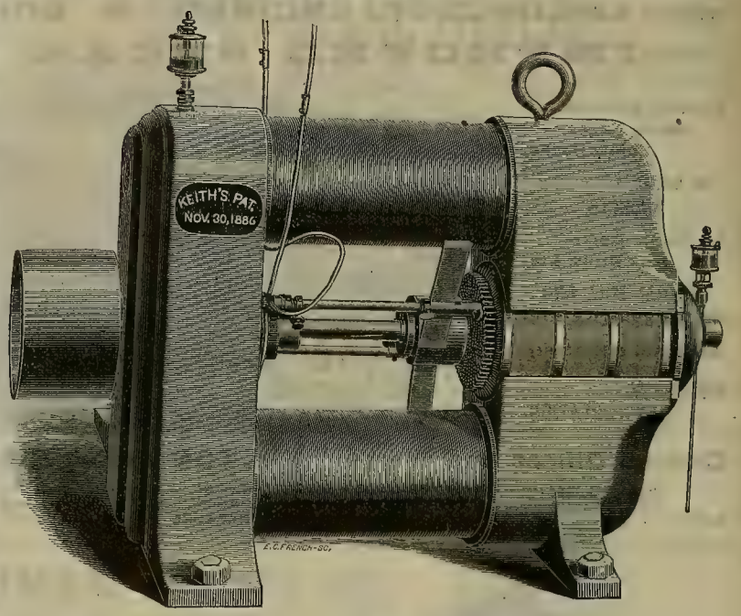
Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1889, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 14th day of May, 1889, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.

OFFICE—No. 327 Pine Street, Room 9 S. F. Stock Exchange Building, San Francisco, Cal.

THE KEITH
ELECTRIC POWER SYSTEM

Is the most Widely Applicable of all.



It is of the highest efficiency, greatest simplicity, cheapest, least liable to damage, gives the greatest return of the power expended at the longest distances.

ADDRESS FOR FULL INFORMATION,

N. S. KEITH,

40 Nevada Block, — San Francisco, Cal.

"ORIGINAL GANDY" BELTING,

Unequaled for any Class of Work.

SPECIALLY SUITED FOR **MAIN DRIVING BELTS.**

A Substantial Guarantee given with every Main Driver.

OUR ENDLESS THRESHER BELTS

ARE UNSURPASSED.

FRENCH & LINFORTH,

Sole Agents for Pacific Coast, - - 35 BEALE ST., SAN FRANCISCO.

—ALSO AGENTS FOR—

ROBERT MANN AXES. T. E. JACKSON HANDLES,

THE EVERLASTING TUBULAR STEEL WHIFFLETREES.

A. T. DEWEY. W. B. EWER. G. H. STRONG.

DEWEY & CO.'S

Scientific Press  **Patent Agency.**

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Every Miner His Own Assayer.

A chemical for testing and ascertaining the value of all kinds of ore, by which every miner and prospector can make his own assays, anywhere in the mountains, at a cost of a little over 5 cents and in a few minutes' time. No apparatus or dangerous acid needed; a dry powder, which may be carried in the pocket. This, mixed with the ore and a little water in a teacup, produces an electric current, which separates the silver from the ore instantly, no matter how refractory. Try it; you will be delighted Will save you many dollars for assaying. Package sufficient for 30 tests, with full directions, by mail to any address on receipt of $2; 12 packages for $10. Address, Prof. J. Herman, P. O. Box 1845, San Francisco, Cal.

HORACE D. RANLETT,

Ores, Mining, and Commission,

420 Montgomery St., S. F.

BUSINESS MANAGER OF

UNION COPPER MINE, Calaveras Co., NEWTON COPPER MINE, Amador Co

Correspondent as Agent for Smelters in London, Liverpool, New York, Boston and Baltimore.

Twenty years experience, in California, purchasing Ores and dealing in Mines.

Special attention given to management and sales of mines and purchase and shipment of copper produce

NO ESCAPE.—A Georgia paper says you may hive the stars in a nail keg, hang the ocean on a rail fence to dry, put the sky to soak in a gourd, unbuckle the belly band of eternity, and lift the sun and moon out, but don't think you can escape the place that lies on the other side of purgatory if you don't pay for your paper.

YOUNG MINING ENGINEER WANTS A position; understands all works in gold and silver mines, mills and chlorination work; is good assayer and surveyor; speaks Spanish, English and German. Address MINING ENGINEER, 1408 Van Ness Ave., San Francisco

California Electric Light Company

227 STEVENSON ST., SAN FRANCISCO, CAL.

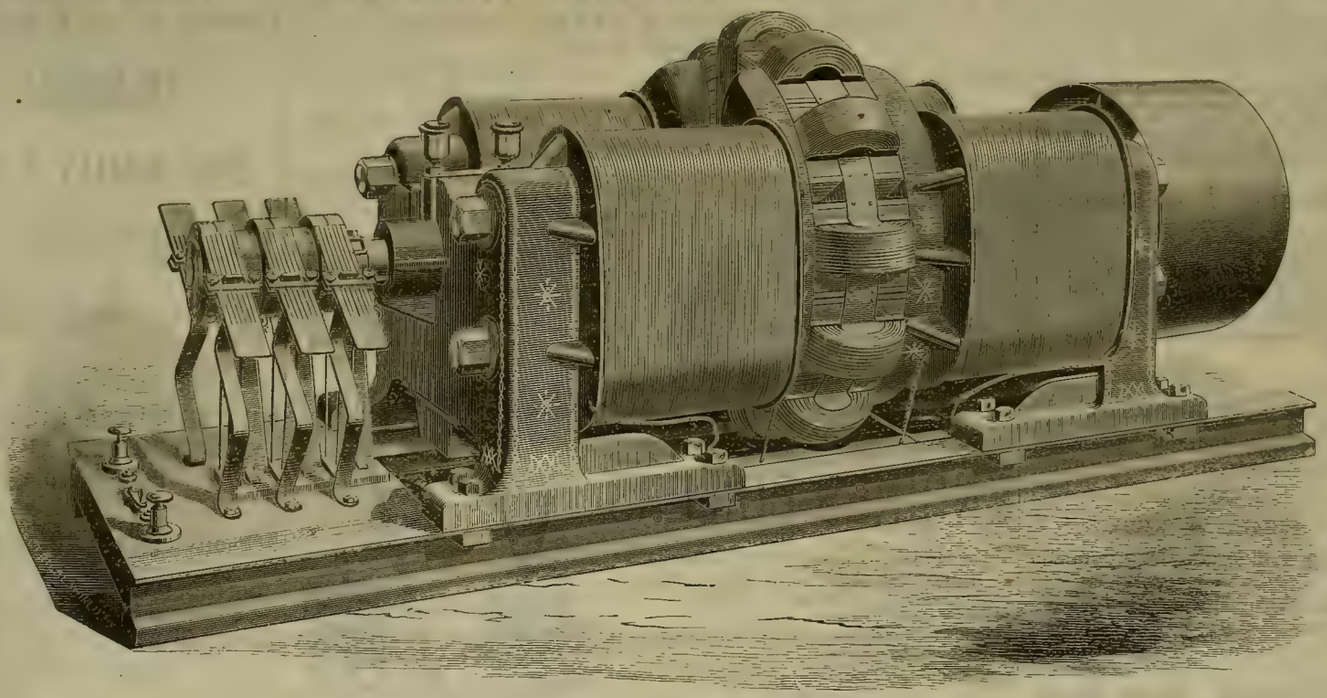
—— AGENTS FOR ——

California, Oregon, Nevada and Washington Territory

For all Apparatus Manufactured under the Patents of CHARLES F. BRUSH, Ph. D.,

KNOWN AS

THE BRUSH SYSTEMS



CONSISTING OF

Arc Lighting Apparatus,

Incandescent Lighting Apparatus,

APPARATUS FOR THE TRANSMISSION OF POWER BY ELECTRICITY,

Long Distance Incandescent Lighting Apparatus by the Alternating System, with the use of Converters,

Solving the problem of furnishing Incandescent Lights at Long Distance from the Dynamo upon small wire, the Brush System requiring wire one-quarter the size of any other.

ESTIMATES FURNISHED UPON APPLICATION.

GEO. H. ROE, Secretary and Manager.

Iron and Machine Works.

CALIFORNIA MACHINE WORKS,
WM. H. BIRCH & CO.,
ENGINEERS AND MACHINISTS,
No. 119 Beale St., - - San Francisco
— BUILDER OF —
Steam Engines, Flour Mill, Mining, Saw Mill and Dredging Machines
Brodie Rock Crushers,
Steam Power, Hydraulic, Side Walk and Hand-Power ELEVATORS.
Manufacturers of B. E. Henrickson's Patent Automatic Safety Catches for Elevators. All kinds of machinery made and repaired. ☞ORDERS SOLICITED.

Golden State & Miners Iron Works.
Manufacture Iron Castings and Machinery of all Kinds at Greatly Reduced Rates.
STEVENSON'S PATENT
Mold-Board AMALGAMATORS,
Golden State Pressure Blowers.
First St., between Howard & Folsom, S. F

THOMAS THOMPSON THORNTON THOMPSON
THOMPSON BROTHERS,
EUREKA FOUNDRY,
129 and 131 Beale St., between Mission and Howard, S. F
MANUFACTURERS OF CASTINGS OF EVERY DESCRIPTION.

C. E. ORTON. J. H. WILLIAMS.
Williams & Orton,
MANUF'RS OF GENERAL MACHINERY.
Works, No. 315 Mission St., San Francisco.
Special attention given to Woodworking Machinery Steam and Gas Engines. Correspondence solicited.

MINING ENGINEERS.

W. A. GOODYEAR,
Civil and Mining Engineer,
MINING EXPERT AND GEOLOGIST.
Address "Business Box A," office of this paper, San Francisco.

ROSS E. BROWNE,
Mining and Hydraulic Engineer,
No. 307 SANSOME ST., SAN FRANCISCO.

ISRAEL W. KNOX,
Mining and Mechanical Engineer
AND PURCHASING AGENT FOR
Mines, Mining Machinery & Supplies.
Mines Examined, Reports and Estimates Furnished, Contracts made, etc.
Office, 237 First St., San Francisco, Cal.

CALIFORNIA IRON YARD.
HENRY J. ROGERS & CO.
Successors to CHAS. CALLAHAN
IMPORTERS AND DEALERS IN
CAST and WROUGHT IRON SCRAP
SECOND-HAND BOILERS AND OLD MACHINERY
Of every description
The Highest Price paid for all kinds of Metals.
OFFICE AND YARD: 128 and 130 Folsom St., S. F
Telephone No. 67.

FRANCIS SMITH & CO.
Manufacturers of
Sheet Iron and Steel Pipe
ALL SIZES.
130 Beale Street, San Francisco, Cal.

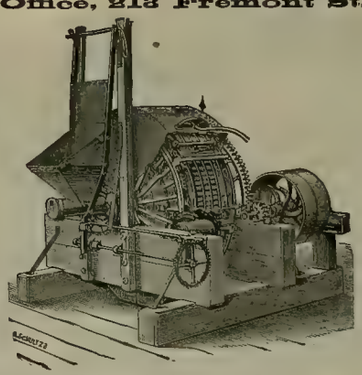
Iron cut, punched and formed, for making pipe on ground All kinds of Tools supplied for making Pipe. Estimates given. Are prepared for coating all sizes of Pipe with a composition of Coal Tar and Asphaltum.

SAN FRANCISCO CORDAGE CO.
(A Corporation.)
Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.
Extra sizes and lengths made to order on short notice.
TUBBS & CO.,
611 and 613 Front St, San Francisco, Cal.

INVENTORS, TAKE NOTICE!
L. PETERSON, MODEL MAKER,
258 Market St., N. E. cor. Front (up stairs), San Francisco.
Experimental machinery and all kinds of models. Tin and brasswork. All communications *strictly confidential.*

PACIFIC ROLLING MILL CO.,
.....MANUFACTURERS OF.....
Cast Steel Castings and Steel Forgings
UP TO 20,000 LBS. WEIGHT.
True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.
GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.
— ALSO —
HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR
LOCOMOTIVE AND MARINE FORGINGS.
ALSO Steel Rods, from ¼ to 8 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shape Steel Wagon, Buggy, and Truck Tires, Plow Steel; Machinery and Special Shape Steel to size and lengths STEEL RAILS from 12 to 45 pounds per yard. ALSO, Railroad and Merchant Iron, Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.
HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.
☞ Orders will have prompt attention. Send for Catalogues. Address
PACIFIC ROLLING MILL CO., 202 Market St., San Francisco.

FULTON IRON WORKS,
HINCKLEY, SPIERS & HAYES, Proprietors.
[ESTABLISHED IN 1855.]
Office, 213 Fremont St., San Francisco.
—MANUFACTURERS OF—

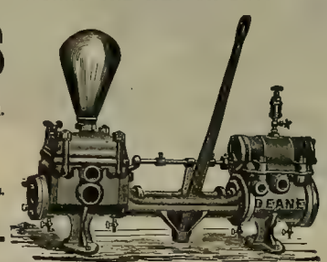


TUSTIN'S PULVERIZER.

MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.
MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air-Pipes.
MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.
MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer
WORKS ORE WET OR DRY.

ENGINES AND BOILERS
OF ALL KINDS,
Either for use on Steamboats or for use on Land.
Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries
OF EVERY DESCRIPTION.
Boiler Repairs Promptly attended to and at very moderate rates.
AGENTS FOR THE PACIFIC COAST FOR THE
Deane Steam Pump.
SPECIALTIES:
Corliss Engines and Tustin Ore Pulverizers.



DEANE STEAM PUMP.
Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.

THE GIANT POWDER COMPANY
Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as
The Safest and Strongest High Explosives in the Market.
GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.
NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and GELATINE-DYNAMITE, Stronger than Dynamite and even Safer in Handling.
JUDSON POWDER IMPROVED.
FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.
BANDMANN, NIELSEN & CO.,
CAPS and FUSE for Sale GENERAL AGENTS, SAN FRANCISCO CAL.

QUARTZ SCREENS
A specialty. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

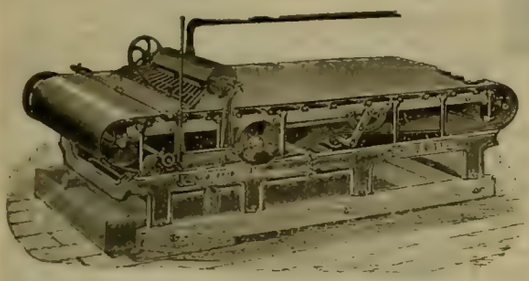
PRICE, FIVE HUNDRED AND FIFTY DOLLARS ($550.00).



THE
"TRIUMPH" ORE CONCENTRATOR.

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

New York Office, 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

54-INCH BY 16 FEET STEEL BOILERS IN 2 SHEETS.

STEAM USERS, ATTENTION!

The engraving represents our standard 54 in. x 16 ft. Boiler. These boilers are made of homogeneous STEEL, and the shell, as shown, being in TWO PIECES, the advantage of this will be readily appreciated by steam users.

There are NO SEAMS in the fire to leak, nor loose rivets to contend with, caused by the continual expansion and contraction of the plate on account of the unequal distribution of the heat under the boiler, the bottom presenting a smooth, even surface which can be easily cleaned. We place a manhole at the back end above the tubes, and one in the front end under the tubes.

The FRONT MANHOLE gives free access to the sheet over the fire, THE VITAL PART OF EVERY BOILER. This point is often overlooked by purchasers, and boilers are supplied with a small hand hole, and the remaining space filled with tubes which allows absolutely no access for cleaning, and in a short time tubes and sediment are one solid mass, and instead of gain in efficiency by a few feet of tube surface, the result is a positive loss.

SPECIFICATION OF BOILER AND FIXTURES:

1 Boiler, 54 inches diameter by 16 feet, with 46 3½ inch tubes; Shell, 5-16; Heads, 7-16.
1 Steam Drum, 36 inches diameter by 72 inches long.
1 Breeching.
1 Smokestack, 30 inches by 60 feet, Nos. 12 and 14 Iron.
300 feet galvanized strand for Guys.
1 C. I. Front, complete.
1 Foundation Plate for front.
1 Set Grate Bars for coal or wood.
1 Back Bar Bearer.
1 Ash Cleaning Door and Frame.
1 Back Arch Plate.
1 Set Binder Braces and Bolts for Brickwork.
1 Stand for back end of Boiler.
1 Steam Gauge and Syphon.
1 Glass Water Gauge, complete, with column and 3 Gauge Cocks.
1 Safety Valve.
1 Stop Valve.
1 Feed Valve.
1 Blow-off Valve.
1 Check Valve.

These Boilers are tested to 150 pounds hydrostatic pressure and are intended for a working pressure of 100 pounds. Total weight of Boiler and fixtures, 17,000 pounds.

☞ BOILERS ON HAND READY FOR SHIPMENT. ☞ SEND FOR CIRCULARS.

Number 13.

Manilla Rope Transmission.

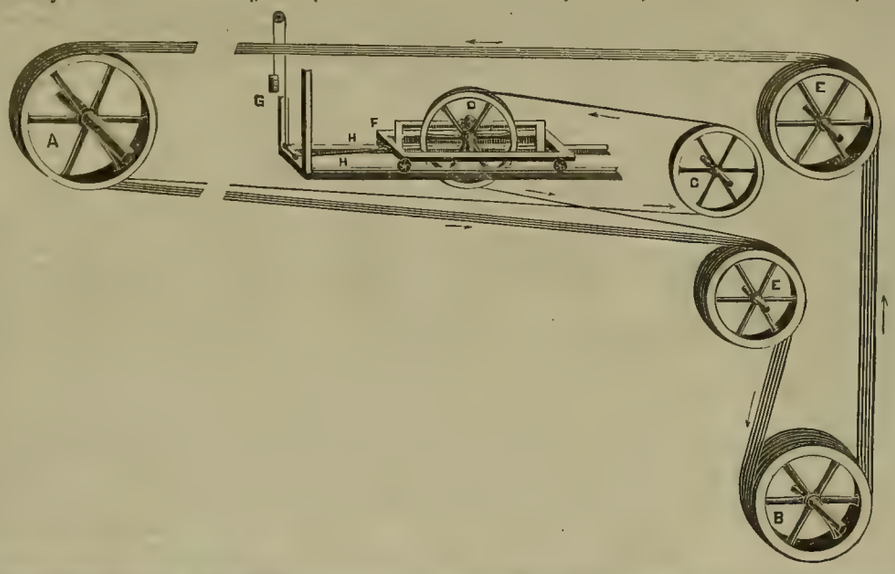
The engravings on this page show the Dodge patent system of rope transmission of power, as applied in the new boot and shoe factory of Buckingham & Hecht, on Twenty-sixth street in this city. Large wood-split pulleys are used. The driver, the driven and the winders have several grooves in which is wound the manilla rope, the number of wraps being used for the purpose of gaining rope surface in contact for the greater adhesion.

In this system the power may be carried to any angle, and shafts may be placed at any angle to each other. The device for taking care of the slack and giving the proper tension to the rope is entirely new and most ingenious. One strand of the rope (the slack side) as it comes from the driving pulley up over an idler, then to a six-foot idler attached to the movable carriage on wheels, takes up the slack of the rope caused by strain and a dry atmosphere, and again pays in slack in case of dampness or other atmospheric changes. It further acts for obtaining a greater adhesion of the rope; and as to tension, the impelling weight attached to the carriage may be increased or diminished according to power required.

The system does away with the annoyance of belts, and the power is transmitted with ease and silence. The manilla rope is "tallow-laid." The power can be taken from the main line at any desired angle, great or small, from one floor to another, on roof or in basement, or wherever needed. The actual strain on the rope is divided by the number of wraps, and is only in proportion to the actual strain required to do the work.

The cuts show the general plan and also the arrangement of details in the Buckingham & Hecht factory, where an Eclipse Corliss engine is used as the source of power. *A* is the main driver on main shaft; *B*, main driven line shaft; *C*, winders; *D*, carriage pulley for slack; *E*, carriers for carrying rope around corner; *F*, traveling carriage on wheels; *G*, impelling or tension weight; *H*, track for carriage.

The Joshua Hendy machine works are agents on this coast for this system. They have applied it at Buckingham & Hecht's, California Electric Light Co., Hooper planing-mills and Hubbard & Co.'s planing-mills in San Francisco; at the Oakland Electric Light Co. and California Door Co., Oakland; the Verdi mill and Essex mill, Verdi, Nevada; the Santa Rosa planing-mills; Front-Street Cable R. R. Co., Seattle, and other places.



THE DODGE SYSTEM OF TRANSMISSION OF POWER BY MANILLA ROPE.

COMSTOCK ORE YIELD.—The ore yield of the Comstock mines during the week ended March 23d aggregated 5553 tons, divided as follows: Consolidated California and Virginia, 2717 tons, battery sample assays showing a value of $35.10 per ton; Savage, 505 tons, assaying $21.37; Hale and Norcross 625 tons, assaying $28.06; Confidence, 658 tons, assaying $27.07; Crown Point, 808 tons; Overman, 301 tons; Justice and Alta, 500 tons; Gould and Curry, 65 tons, assaying $19.28. The bullion yield of the above was about $140,000.

MINING SUITS.—The Benton Consolidated M. Co. has sued W. S. Wood, as executor of the estate of Seth Cook, to recover $15,000,000, the alleged value of 150,000 shares of stock in the corporation. The same corporation has sued the Alta M. Co. for an accounting, alleging that the Alta people, who had the control of the Benton mines, appropriated $200,000 to their own use which should have been credited to the Benton Co.

WORK on the $100,000 reservoir, to be built by the State of Nevada on the Carson river, will soon be commenced. The construction of this reservoir will provide ample motive-power for the Carson river stamp-mills throughout the year.

THE Carrizo gold-fields are attracting men from many towns in Arizona.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

Ruby City Mines.

EDITORS PRESS:—Your paper reached this remote part of the country at last. Owing to the irregularity of our mails at times, we are deprived of news for several weeks. At present a new line of stages has been running from Spokane Falls to Ruby City twice a week, and will undoubtedly give us news from the outside more regularly.

It may be of interest to the readers of the PRESS to know how to reach this new mining camp. As yet, there is but little mentioned of it in papers. Ruby mountain, in which the mines are located, is situated northwest 162 miles from Spokane Falls, that being the nearest railroad to this camp at present. It takes then three days' ride by stage, in which the traveler has a full view of the highly-spoken-of Big Bend country. The traveler crosses the Columbia river at Condon's Ferry, thence across the Indian reservation, now occupied by the great warriors Moses and Joseph. After traveling 25 miles across the reserve the Okanogan river is reached at a distance of 24 miles from its mouth, running into the Columbia. Thence one goes up the Salmon river or Conconully creek to Ruby City. The charges from Spokane Falls are about $20. This place is also reached by stage in the summer season from Ellensburg at a distance of 175 miles. The difference between the two routes is very little in distance or time.

Our mining boom has just started. The Arlington mine takes the lead as usual. The company will erect a plant this summer of about 50 tons' capacity daily. Weather permitting, work will commence the early part of April. This mine is opening up splendidly. Weekly samples taken from an average of the ledge at each place worked give very satisfactory returns, with an increase of gold as depth is gained. The entire ledge will yield by working test about $64 per ton in silver; gold, from $10 to $12. Assays at times go as high as $27 per ton. This is considered the best property in the camp for the reason it is the most extensively developed.

The 4th of July, situated a little to the northeast of the Arlington, has been sold to a Montana company. The sum paid for it I did not learn. They purpose to put on extensive machinery and sink the present shaft to a depth of 300 feet. It is now down 75 feet. This enterprising mining company of Helena, Montana, will give great courage to the prospectors of the camp generally, as all that is needed is time and money to make this camp second to none on the coast. The War Eagle Co. have also started operations. This property is owned by St. Paul capitalists, and they intend to operate extensively this summer. The work is under the superintendency of Capt McCafferty, a practical go-ahead mining man. Their intention is to sink and drift. Machinery will also be erected for hoisting. Several other claims will be in operation. Among the most permanent claims is that of the Lone Star, situated about four miles north of the Arlington mine, near Conconully City. The mine is owned by a company from Tacoma, who are now engaged in sinking by means of a donkey engine and a small-sized steam pump. The prospect is good. At or near the mine is a concentrator already in operation concentrating ore from several different mines in the vicinity. It has a capacity of 25 tons daily.

Everything shows favorably for the opening up of a large mining camp this summer. The city of Loup Loup is a thriving little town which will be the main trading post for the greater number of the mines. It is reached by wagon-road from the Okanogan river, a distance of 14 miles; but we will soon have the iron horse near the town, as the N. P., also the Lake Shore and Seattle railroads are fast approaching. MINER.

Ruby City, Okanogan Co., W. T.

Nitro-Glycerine Cannon.

EDITORS PRESS:—J. P. Cizek of Vallecito, Calaveras county, Cal., is the inventor of a nitro-glycerine shell and a cannon constructed to fire the same with safety. By the peculiar arrangement, this principle when applied to guns in use increases their range on an average two miles. In consequence, the range is not lessened as in the dynamite guns, but increased. Another feature, which will be admitted is of the most importance, is the fact that the shell can be discharged at any desired angle or in a direct line. The cannon is self-cleaning, and its construction admits of 120 shots being fired in one hour. The construction is such as to make it almost automatic in its operation. The chief execution, however, is by the shell. No special make of powder is required in driving the shell, which once it has reached the object to be demolished, explodes by concussion. The destruction is in proportion to the size of the cannon and corresponding shell, Mr. Cizek putting the average charge at ten pounds. In this invention, Mr. C. claims to have solved the question of America's defense from foreign navies. With a range increased, the ability to fire at any angle and the well-known power of nitro-glycerine, Uncle Sam once supplied with this new weapon of destruction, could bid defiance to the combined navies of the world.

A single shot would suffice to sink the stoutest war vessel. For want of the necessary capital, Mr. C. has not been able to bring his invention before the proper authorities and have it given the test and publicity it deserves. As a patriotic American, he makes this proposition: "I will allow the U. S. Government to make a cannon after my model. I will furnish instructors and plan of shell. If when tried, the gun proves effective and is adopted, Congress to give me what that body may think is justly due me for the invention, the Government to be at all expense in the manufacture and trial of the gun." To prove the effectiveness and safety of the invention, Mr. C. has applied it to a shot-gun, with which he fires a distance of 700 yards, penetrating a two-inch plank at that distance. Inasmuch as the gun and shell are not patented, I am not at liberty to describe the manner in which the increased velocity of the discharge or the rapidity in firing the nitro-glycerine is accomplished. I only ask some one of our representatives in Washington to bring the invention to the notice of the war department, and give California the credit of producing a weapon of destruction that once placed in position, will enable America to exchange her present defenseless harbors into Gibraltars of defense. E. F. SCHAEFFLE.

Southern California Mines.

EDITORS PRESS:—The Kentuck mine, in the Julian mining district, was sold last week for $25,000. Mr. D. C. Kling, a St. Louis expert, bought the mine in the interest of a St. Louis syndicate, who propose to commence developing the mine at once by running a tunnel and erecting a mill. This mine was prospected several years ago by two shafts and some crosscuts.

It is stated by San Diego papers that Gov. Waterman has refused $3,000,000 for the Stonewall, which is in the Julian district.

The report of the State Mineralogist has been of incalculable value to Southern California, as it corrects a number of misapprehensions which capitalists and others have formed in regard to this country.

We have within 100 miles of Los Angeles some as fine prospects for paying mines as can be found in the State, and now that the "boom" in town lots is over, capitalists are beginning to invest in mines.

We were shown some specimens of gold-bearing quartz the other day which showed free gold all through it and assayed away up, yet because it is not in Lower California we hear of no rush in that direction. The ledge from which they were taken is 14 feet wide and runs from $10 to $60 in free-milling ore. The owners are developing it right along. It is strange that people will rush off to Santa Clara or Old Mexico when there are just as good quartz mines close home and whose owners they see every day, but who, owning valuable property which can only be injured by any such craze, are not given to "blowing" or "booming" it up. P.

Mineral Resources of Nevada County.

EDITORS PRESS:—We started about the 1st of December on a sort of geological expedition to study the mineral resources of Nevada county, and also to collect for museum purposes. The mineral districts which we have visited are important mostly for their quartz and gravel mining. You are kept pretty well posted on these specialties. We are satisfied that the quartz industry is only partly developed, and that the gravels will afford work for active hydraulicking for more than 100 years to come.

It is our opinion that the Government can well afford to make liberal appropriations to secure the working of these mines, in view of the great revenue which will be the result. From what we have seen we are satisfied that this county has many rich quartz and gravel mines. There are, however, many other resources which must, in the near future, be considered as sources of wealth. We find chrome iron, iron ore, copper and manganese, magnesite in considerable quantities, and some indications of cinnabar, with unmistakable indications of iridium. We have seen considerable good granite for building purposes, also two or three varieties of marble.

There are considerable quantities of kaolin or fire clay. There are some five varieties of agate, bloodstone, and opalized fossil wood, good for polishing.

We have not as yet had a good chance to study the geology of the country, but have made some observations. We find impressions of leaves in the kaolinite of the gravels; also in a kind of primary coal formation at Moore's Flat, and in the volcanic mud formation at North Bloomfield; also in the brown iron or sulphureted cement at North Bloomfield. We have been shown several fossil impressions from other localities. The impressions seem to be mostly resembling black oak, live oak, willow, alder, manzanita and maple. We have seen several varieties of fossil wood showing the borings of insects. We hope to be able in the near future to give you some more items on the resources of this county. A. K.

Separations.

[Written for the PRESS by C. H. AARON.]

Cadmium from Zinc.

In acetate and probably in acid and neutral solutions generally, except thiosulphate, and in absence of ammonium salts, cadmium is precipitated by sodium sulphite while zinc remains dissolved. The precipitate dissolves in aqueous sodium thiosulphate.

Copper, Nickel and Cobalt from Zinc and Cadmium.—In this sulphate solution, by potassium xanthate, the cadmium and zinc remain in solution. Ammonium salts do not interfere. In some other solutions cadmium is precipitated by potassium xanthate and is not then redissolved by aqueous sodium thiosulphate.

Copper, Nickel and Cobalt from Each Other. The mixed xanthates are washed with dilute ammonia as long as that yields a yellow precipitate with acetic acid, which reprecipitates the nickel xanthate, though it is generally necessary to add a little more potassium xanthate to complete the recovery; 19 6 per cent nickel. The copper (cuprous) and cobalt xanthates remaining on the filter are washed with aqueous potassium cyanide as long as that gives a yellow precipitate with acetic acid, which reprecipitates the dissolved cuprous xanthate; 34.85 per cent copper. The cobalt xanthate remains on the filter; 19.6 per cent cobalt.

The cuprous xanthate may be washed finally with alcohol or with ether, the nickel and cobalt xanthates with water; they are partly soluble in alcohol and in ether. However, the cobalt xanthate may be washed with ammonium if desired for quicker drying. All three may be dried on the water-bath for the weighing, or they may be calcined to oxide.

The separation must be made without previous drying of the mixed precipitates, as, when once dried, it is almost impossible to wet them thoroughly, even with the aid of alcohol, and the separation cannot be perfected.

Richmond Consolidated.

Richmond Consolidated shareholders have held their half-yearly meeting. The production from 4573 tons of ore has been 2325 ounces of gold, 97,054 ounces of silver and 452 ounces of lead, of a gross value of £40,073. The directors have very serious news to report to the meeting. They state that "the United States Government having commenced suits against the Richmond, the Eureka Consolidated, and other mining companies and individuals in the State of Nevada for the value of the wood used by them for mining purposes and cut from the public domain, both the Richmond and the Eureka Company have found it necessary to close down their works and suspend all mining operations. Rumors of these suits have been prevalent for some time, but no one supposed that the Government would ever authorize such proceedings, which, if persisted in, must of necessity paralyze and destroy the mining industry of the State, and throw thousands of persons engaged in mining operations out of employment. For years it has been the custom to cut and use for mining purposes the wood, which, in this district, is not suitable for lumber, but is of a stunted and scrubby growth of little or no value, except for fuel, and without which the mines could not have been worked.

"The Richmond Company has been in operation about 16 years, and for the Government to lay by all this time and to raise this question now is most astonishing. The value of the operations of the Richmond Company to the State may be realized from the fact that since 1871 no less than £4,450,000 had been expended by them, principally in wages and materials. In addition to this the company had established in Eureka very extensive reduction and refinery works at a cost of upward of £100,000, thereby creating an entirely new industry, and it is not too much to say that the Richmond and Eureka Consolidated Companies together have been the principal cause of the prosperity of the town of Eureka, and made it today the second town of importance in the State. The amount claimed by the Government in respect of the wood exceeds the total amount of the profits made by the company, which means, in other words, that had the company been called upon to pay for the wood at the price now set upon it by the Government, it would have been working throughout the whole time at a loss. These proceedings of the Government have caused the greatest consternation throughout the State. The shareholders having at the last meeting approved of the suggestion that a portion of the reserve fund should be invested in the purchase of another mine, Mr. Probert has examined several, but has not yet found one that he can recommend; in the face, however, of these timber suits, it behooves the company to be very careful how they invest any further capital in the United States."
—*Mining Journal.*

J. MCROBIE, manager of the Western Union Telegraph Co. in this city, has been appointed superintendent of the American District Telegraph Co., vice H. G. Phillips, resigned. Mr. McRobie has also been appointed superintendent of the Gold & Stock Telegraph Company. He will hold both of these positions in conjunction with his position as manager in this city of the Western Union Telegraph Company.

How Roads Are Made in Santa Clara County.

Many of the counties of California should make immediate and adequate efforts to secure better roads. Probably this fact will press itself home upon the attention of our readers who have been required to travel to and from their market towns since the recent glorious rain. The same facts will enforce themselves again next summer, when the sea of bottomless mud is transformed into a desert of deep dust begemmed with chuck-holes. The way some counties neglect the making of proper highways is reprehensible. They are not the poor, undeveloped counties, either, but some of the richest in the State. Even in some fruit regions, where development has progressed farthest and the hauling of tender produce would seem to demand the finest roadways, the very worst in the State are to be found. There is even land valued at $300 to $1000 per acre which is situated alongside of a slough in winter and a dust mine in summer. Both good repute among visitors and actual hard profit to resident fruit-producers demand better roads.

Some localities are better situated than others to secure good roads cheaply because road-making materials are handier in some regions than others, and yet something should be done even where rock and gravel are most expensive. Santa Clara county has the reputation of being one of the counties having the best roads and keeping them in the best condition, and it will no doubt be both interesting and instructive to our readers to know how Santa Clara county roads are made and cared for. The Marysville *Appeal* recently secured from W. O. Watson, one of the supervisors of Santa Clara county, a statement of the way his county's roads are improved, from which we quote as follows:

"Public roads in this county run over all classes of soil—clay, sandy loam, adobe, gravel, red loam—all needing a different treatment as to grade, amount of gravel or macadam and drainage. The general method used here, in making new roads, is to grade the road first, and for that purpose we use three kinds of scrapers. For filling up large holes or very uneven places, we use the common two-horse scraper in general use; also the late improved two-horse scraper that runs on wheels, which for heavy grading is economical and a great improvement over the common ones.

After the road has been graded with the above-named scrapers, we then plow the sides of the road, turning as many furrows as are needed to make the necessary grade. We then take the large road grader (McCall pattern), using ten horses, and throw the sides, already plowed for that purpose, to the center, making, when finished, a complete grade smooth and uniform in character.

When the road is completely graded, as above described, it is then ready to receive the gravel or macadam, as the case may be. The usual amount of gravel or macadam used on new roads is about four cubic yards to the rod. The cost of grading and graveling roads depends largely upon the character of the soil over which the road runs, and the distance the gravel has to be hauled to cover the same. This county is well supplied with gravel, within convenient distances to nearly all of our roads. Our experience is that no soil except gravelly soil will make a good road that will stand much travel without being well graveled or covered with macadam. In some of our main avenues where converging roads center a great amount of travel, nothing but good trap rock, broken to proper size, will stand the traffic.

In the past few years our county has entered upon a system of sprinkling the public roads, where water can be obtained conveniently, which greatly improves the roads and at the same time makes them very pleasant to public travel. This system of watering the roads in the dusty season is somewhat more expensive than not to water at all, but the pleasure and convenience is so great to the traveling public that the taxpayers do not object to the greater expense. This county spends annually on the public roads $80,000."

These statements will be found of wide value. Of course local methods will depend upon local conditions. The general principle is to do something effective, and to do it before the State gets much older.

MINERALS ON RAILROAD LANDS.—The Commissioner of the General Land Office has indorsed Receiver Linthicum's decision in the case of the C. P. R. R. vs. S. V. Valentine, the Big Oak Tree mine case. The decision gives title to mining claimants on "odd sections" of railroad land in this State. In effect it decides that the railroad company was *not* entitled to minerals on the sections granted to it by Congress. The case will be appealed to the Secretary of the Interior.

THE names of over 100 men are now on the pay-rolls of the Pioche Con. and Yuba Mining Companies, and upward of $10,000 per month is disbursed. A few pay-days at this rate and the effect will be generally felt.

THE Lost Confidence mine, Iron Mountain, Shasta county, which is referred to more at length in another column, has this week made its first shipment of silver bullion since the cave last fall.

Another Bearing Date Palm.

In our issue of February 16th we gave a large photo-facsimile of a bearing date palm and its companion staminate tree in the garden of J. R. Wolfskill, near Winters. The facts there recited concerning the date palm in California have also a bearing upon the handsome engraving on this page, and the reader is referred to them.

The picture presented herewith is a reproduction by the Dewey Engraving Co. of a photograph taken last fall by W. R. Nutting. The observer looks toward the northwest and the distant hill-outline is the crest of the Coast Range northward of Putah canyon. The foreground is on the farm of the late S. C. Wolfskill, now owned and conducted by his wife and children. The interest centers in the row of date palms which are the most prominent feature of the picture. These trees sprang from the seed of the date of commerce and still stand in nursery row as they were first set out. The first fruit was borne in 1877 when the tree was about 12 years old, the date of bearing and the age of the trees agreeing closely with the fruiting of the tree shown in our issue of February 16th. It was the fruit from one of the trees in this picture which was shown at the Mechanics' Fair of 1877 as the first California grown date brought to public notice. It was one of the trees from this row which was taken up by W. G. Klee, and planted out on the grounds of the New Orleans World's Fair in 1885, the tree surviving well its removal and long journey to Louisiana.

As the engraving indicates, the trees have suffered by their close association in the row, and are not as shapely as the trees in John Wolfskill's garden, where they have more room and rather better treatment.

The picture shows the tree in fruit, its heavy clusters emerging from the base of the leaves. The fruit in this case is a bright yellow, rather more than an inch in length, and it is a later maturing variety than the tree shown in our earlier engraving. Some seasons are, however, propitious for its ripening, and the fruit is highly esteemed by the family.

BEARING DATE PALM ON THE FARM OF MRS. S. C. WOLFSKILL, NEAR WINTERS, CAL.

Eastern Nevada.

Mr. David C. McQuitty, Assemblyman from White Pine county, Nevada, who recently visited Salt Lake City, gave the *Tribune* editor the following confirmatory testimony as to the character of his part of the State. He has lived at one time or another in nearly all the towns he names and in some others, grown cattle and horses, been in trade, worked mines, and traveled all over the State and through to Los Angeles and back on the general route of a railroad to that point. A divide about 6000 feet in altitude zig-zags across the State in the vicinity of the 40th parallel, whence the drainage is north and south. This is the mining belt as well as the arable and pasturage belt, full of springs, the mountains broken, presenting frequent passes feasible for railroad purposes. His idea of a line is to swing around the north end of Shell creek range and go up Steptoe valley to and through Hercules Gap in Egan range into the upper end of Long valley; thence over low hills into Newark valley, leaving Hamilton a dozen miles to the left; from Newark valley on by way of Fish Creek valley south of Eureka, Hot creek, Stone Cabin and Ralston valley; down the latter east of Death valley to Ash Meadows, and then to Mojave or Barstow, preferring the latter, using the A. P. line to Los Angeles for a time and finally building through.

Mr. McQuitty says the Deep Creek, Antelope, Shell Creek, and Egan ranges are mineral bearing for a hundred miles in length, and the roads would have mining districts and towns on either hand within 5 to 20 miles from Deep Creek to Ralston Valley. Following are capital towns of mining districts: Cherry Creek, Shellburn, Taylor, Ward, Ely, Mineral City, Hamilton, Treasure Hill, Seligman, Eureka, Hot Creek, Reveille, Belmont, and Tybo. At Seligman a $240,000 reducing plant was completed only last year. Mr. McQuitty says that Ely alone would send in 100 tons a day of $60 ore. Ely and Seligman are base bullion districts.

There are, without doubt, 20 districts within 200 miles of the city, and that would be 5 to 25 miles from the railroad, which would furnish three or four carloads of ore a day, and, inclusive of coal, as much outward freight.

SOME eight or ten men are now employed in removing the machinery from the Grand Prize mill, says the *Times-Review*, preparatory to tearing down the building and the erection of concentrating works upon the site of the present structure. The plans of the new works are completed, and the use of the mill foundations, which are solid and just suited for the purpose, will materially lessen the cost of construction by rendering a large amount of grading and mason work unnecessary. A trial test of 200 tons of concentrating ore from the Prize has just been completed at the Queen works, which proved highly satisfactory, working up to a high percentage.

THE ELECTRICAL SOCIETY.—The principal feature of the third meeting of the California Electrical Society at B'nai B'rith hall was a paper by F. M. Speed entitled "The Work on an Electric Circuit." The president, N. S. Keith, on behalf of the Executive Committee, reported progress in the negotiations pending between the society and the Mechanics' Institute, which have the making the society a branch of the Institute in view. Both bodies look favorably upon the proposition.

THE KENTUCK MINE SUIT.—The defendants in the case of Washington Smith vs. Wales L. Palmer, C. C. Stevenson and the Kentuck Mining Company have filed their second amended answer. They deny specifically all the allegations set forth in the complaint in relation to the manner in which it was charged Governor Stevenson managed the affairs of the company.

THE suit of Charles Forman vs. the Overman Mining Co. to recover $6000 for salary as superintendent, was concluded in the district court recently, the jury returning a verdict in favor of the plaintiff for the full amount claimed.

THE Eureka Con. Company will soon receive some 700 tons of coke, several carloads of which arrive by every train. This indicates that their furnaces will start up in the near future.

Minerals on Railroad Land.

The Big Oak Tree Mine.

Some months since the *Examiner* published in full the decisions of Register Hetzel and Receiver Linthicum of the Sacramento Land Office in the case of the Central Pacific railroad vs. S. D. Valentine—a contest hinging on the question of whether or not the railroad company was entitled to the possession of mines and mineral lands developed on the odd sections granted to the corporation under the Act of Congress of July 1, 1862. The Central Pacific Company claimed, of course, that the title to the entire area of the "odd sections" was vested in them, whatever the character of the lands, which proposition the defendant, who had bought the Big Oak Tree mine from the locators, William Morry and associates, claimed to be negatived by the provisions of the mining law. The particular claim in question is situated about 1½ miles northerly from Colfax, Placer county, on a vein running parallel with the rich Rising Sun mine, but the principle involved in the contest was of course of far greater importance than the mere value of the individual piece of property at issue.

The two decisions from the Sacramento Land Office, of which mention has been made, were delivered September 24, 1888, that by Register Hetzel finding for the railroad, while Receiver Linthicum's was to the effect that the mineral claim of Mr. Valentine was just. According to the rule where there is a conflict of this kind, the matter went to Commissioner Stockslager of the General Land Office at Washington, who on Tuesday indorsed Linthicum's decision in favor of Valentine.

This result of the contest will be received with unbounded satisfaction by the mining men of the State, as virtually settling all the other similar cases, of which there are many. It is probable, however, that the railroad company, before abandoning a point upon which hinge such important interests, will carry the matter to the Secretary of the Interior himself, whose decision will be final.

THE West Granite mine, Phillipsburg, M. T., has been purchased by St. Louis capitalists.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

GOLD AT THE MISSION PEAK.—*Reporter*, March 16: The scent of gold and silver traces recently discovered in the hills near Mission Peak, brought a number of mining experts to view the prospective lode. That there is gold in Alameda county was known away back in the early days, for the Mission Indians frequently brought nuggets and gold dust to exchange for commodities at the store at Mission San Jose. Several organized attempts have been made to find the ledge, but without success.

Calaveras.

THE UNION MINE.—Calaveras *Prospect*, March 16: While on our way from Angels last week we stopped at the Union mine to ascertain if possible what was being done on the new lead. We found that there had been work done on three shafts, two of which were being worked, while at the third or south shaft there is not much work being done at present, but we understand the company will commence sinking on the last-mentioned shaft in a short time, or as soon as hoisting works can be put up. The north shaft which is near the old Irvine waterwheel on the bank of Calaveritas creek is down about 90 feet. The ledge looks well and the prospect is satisfactory to the owners. At this point the ledge is several feet wide and the ore is of a good quality. The middle shaft is about 400 feet south of the north shaft near the road leading to the old Union mine. This shaft is down about 65 feet and has three compartments. At 60 feet the vein is 15 feet wide and the rock looks well and prospects well too. The south shaft is about 40 feet deep and work will be resumed on it in a short time. The machinery for the hoisting works is already on the ground. This shaft is at least 600 feet from the middle shaft and the vein looks well at this point. A 10-stamp mill will be built as soon as the lumber and machinery can be put on the ground.

MILL COMPLETED.—*Prospect*, March 22: The sound of a clatter of stamps coming from the direction of Fourth Crossing the forepart of the week, attracted our attention. The sound came from Rathgeb's mill, one mile from the Union mine, near the Darnel ranch. This mill has been in process of construction for a year past and has just been completed. The ground is laid off for a 40-stamp mill, but at present 20 stamps are used. Six hundred tons of rock and decomposed quartz that are now on the dump is being crushed. As soon as this quartz is crushed the owner of the mill intends to hoist out the water that is now in the shaft by means of a skip and then go to sinking on the lead. The shaft is about 100 feet deep. They have a large body of ore, but do not know exactly how wide the vein is. The rock is of good quality and carries considerable sulphurets. All the machinery of the mill and hoisting works is new and of the latest pattern, including a steel boiler set in cut soapstone and cemented. The engine in the mill is 50-horse power and the hoisting engine and gearing is heavy enough to sink the shaft 600 feet. Everything about the works is solid and substantial. Mr. Lem Wilcox superintended the putting up of the machinery.

El Dorado.

AN IMPETUS.—Cor. S. F. *Call*, March 19: An impetus has been given to mining in El Dorado by the reopening of the Pacific mine, which has been closed down for the last seven years. This mine is situated on what is known as the Greenstone or mother lode, running north and south through Calaveras, Amador, El Dorado, Placer, and Shasta counties. The richest and most extensive mines developed in Northern California have been found on this belt. Other and rich deposits are found on ledges running parallel with this lode. New locations are being made, and old deserted shafts are being cleaned out, and a revival of the mining interest is being prosecuted all along the line. One of the most practical and enterprising schemes in operation for thoroughly prospecting these ledges is that adopted by the Big Tunnel M. Co., organized for the purpose of running a tunnel 3000 feet across 18 well-developed ledges, including the mother lode. The tunnel is 6x7½ feet, and they have run 552 feet, cutting through three gold-bearing veins that will pay to mill. The mother lode is 1700 feet from the mouth of the tunnel, and will be crossed 1200 feet below the surface. They have just cut through a ledge of slate 55 feet wide, which is pronounced by experts the finest quality of slate in the world. The ledge is cut 350 feet below the surface, and this immense body of slate, free from iron, sand or any foreign substance, can be easily mined in blocks of any desirable size, and can be split into sheets not thicker than blotting paper. It is firm, smooth and sufficiently hard to polish—equal to marble. This ledge is the same as that upon which Mr. Mothersol has been operating for the past year (one and a half miles distant) and from which he shipped 22 car-loads of 20,000 pounds, 11 car-loads of which has been used by the Southern Pacific railroad for roofing their depot buildings. The demand for this slate is constantly increasing.

TAILINGS.—Placerville *Observer*, March 23: Mr. Potts, at the Granite mine, Smiths Flat, in washing up a pile of tailings finds nuggets of gold weighing as high as $12. At the Bassett mine at Weaver hill, in the North tunnel, now in 80 feet, gravel is being taken out that shows free gold in every carload. At the Gignac mine activity prevails. The mill is up and the machinery will soon be in position. The head carpenter of that institution, Mr. Stone, is a rustler.

THE SUPERIOR.—This mine is situated about three miles south of Placerville, and has three parallel veins on the mother lode. An ore chute on the footwall vein has been explored for a distance of 150 feet, with pay ore in the face, the width of the vein being from 2½ to 10 feet. The upper tunnel crosses the formation 80 feet below the surface. The lower tunnel, following the formation southerly, is in 700 feet, giving a depth below the surface of 160 feet. The two exploring tunnels aggregate 950 feet. They have a shaft down 180 feet deep on the incline. This mine was worked in early times before the reduction of ores was understood as it is at the present day. Further south than any developments have been made, there are heavy croppings on the surface for hundreds of feet, which is an indication that a larger ore body will be found than has yet been encountered.

JOSEPHINE.—The Josephine mine, situated about eight miles northeast of this city, was attached by a few of the impatient hands employed by Supt Dauvenspeck, on Friday last. Sheriff Anderson and Attorney Bennett came over from Placerville Friday and went through the mine. We understand the amount for which the attachment is levied is $1300. It is our belief that the debt will be paid, and the Josephine, which we have reason to believe is one of the best mines in the county, will have men at work again by the last of April. They were working on No. 5 tunnel, and by pushing along on low-grade ore for three months would strike the pay chute, when a still larger force would be put on, and we hope and are confident that some of the vast amount that has been expended will come back into the pockets of the owners. In the last year the mill has been increased to 20 stamps and eight new concentrators put on, and in fact they have now got it in good condition to develop. We understand that the pay chute is 600 feet long in tunnel No. 4.

NEW LOCATIONS.—Placerville *Observer*, March 19: A vigorous policy is being pursued by our miners. New locations are being made, and old shafts are being repaired and cleaned out preparatory to thorough and systematic working. Lively times will be seen in the near future.

BIG TUNNEL.—One of the most practical and enterprising schemes in operation for thoroughly prospecting these ledges is that adopted by the Big Tunnel Mining Co., which has organized for the purpose of running a tunnel 3000 feet, cutting across 18 distinct ledges, including the mother lode. Their tunnel is 6x7½ feet, and they have already run 552 feet, cutting through three ledges, the rock from any one of which bears gold and will pay to mill. The mother lode is 1900 feet from the mouth of the tunnel, and will be crossed 1200 feet below the surface. They have just cut through a ledge of slate 55 feet in thickness, which is pronounced by experts to be the finest quality of slate in the world. The ledge is cut 350 feet below the surface. The Big tunnel is situated one and one-half miles from the Sacramento & Placerville railroad depot and is easy of access.

THE BASSET.—This mine is situated two miles south of this city, and was noted in early times for its rich crevices. As high as $7000 were washed out in one day by two men. Later a hydraulic was placed on the ground and the front rim washed off as far as it could be on account of the hardness of the gravel. A small mill was erected which was so imperfect that only the coarse gold could be saved. A tunnel is now being run on a west bench which is showing blue gravel which prospects rich in gold of a heavy character. This gravel will require machinery for reduction.

THE GIGNAC.—Active operations have been commenced on the Gignac cement gravel mine. Several men are at work opening the mine, track is being laid, a fine car has been made at the Placerville machine shop, lumber has been delivered on the ground from the Blair Bros.' lumber yard. Carpenters are at work building a mill, which will soon be in operation, when we shall look for good results. The gravel in this mine is known to be rich, but is too hard to be worked by the ordinary process of sluicing.

OAK RANCH DEEP GRAVEL M. CO.—This company has about completed an incline to strike a bench of gravel west of the main channel, which was partially prospected in 1851. At that time the gravel paid about $5 a day to the man for drifting and washing in sluices, which was not considered remunerative at that time. It is the intention of the company to thoroughly open this bed of gravel, which is thought to be extensive, and arrange for having it worked in a mill.

THE ROGERS.—This mine is situated near Smiths Flat, and is one of the oldest mines on that range. Supt. Coughlin is now running a drift north from the main works to strike a west bench, when good gravel is expected to be found. He is also making an upraise to strike an upper drift in order to get good air. They are now breasting out some good gravel from another part of the mine.

YOUNG MINERS.—Dozens of boys have been busy between showers, during the past week, with pans and scrapers, working out the wagon ruts on the old emigrant road, near its intersection with Main street in Upper town. They find considerable gold along the road when the loose dirt has been washed off by the heavy showers of rain.

THE GRANITE MINE.—Mr. Potts, owner of this mine, is preparing to wash a body of tailings which have accumulated from washings of gravel from the drifts in the mine.

Fresno.

THE HILDRETH MINES. — Fresno *Expositor*, March 13: Jesse Morrow returned last night from his mine near Hildreth. He is working 12 men in the tunnels of his mine and is putting up the hoisting works. The ledge is two feet four inches wide and the rock assays from $40 to $100 a ton. At the Abbey mine they are working 60 men. At the last cleanup the other day, 18 days' run, $11,700 was realized. The Wilsons, husband and wife, are mining a one-horse arastra and cleaning up $100 a week. The Last Chance mine is looking up. Some very rich prospects have been recently discovered. At the Temperance Flat mine, Sherwood & Co. are running a two-horse arastra. But by far the largest and most important developments recently made in the district—developments which promise to be a bonanza—are those in the old Jim Harron mine above Newt Murphy's. This mine was sold for $300, and recently $20,000 was offered for it and refused. The strike made in this mine is one of the richest ever made in the district. The ledge is two feet four inches and free gold can be plainly discerned all through it. There is enough rock in sight to make its owners handsomely well off. There are many strangers and mining experts throughout the district looking for mine land bargains.

Los Angeles.

A QUARTZ-MILL.—Los Angeles *Herald*, March 26: The existence of gold in the canyons above Newhall has been an established fact for many years past, and placer claims are worked there regularly every spring by Mexicans who, however, quit when the water gives out, for the mines are then no longer profitable. This continuous prospecting has revealed the fact that, in addition to the placers, there is gold-bearing quartz averaging, say $10 or $15 a ton, and a few weeks ago Messrs. Sanford Johnson and Ed Dunham started in to work on an idea that has long been talked about but not acted upon. The scheme is to put up a large quartz-mill in the center of the gold district, for as soon as this is done prospectors and miners will flock in from all directions and the venture will undoubtedly be made a paying one. After careful consideration and due investigation, Messrs. Sanford & Johnson decided to embark part of their fortunes in the speculation, and left for the North last week for the purpose of obtaining the necessary machinery. The machinery will be shipped down and put in position as soon as possible. The location of the mill will be about 12 miles above Newhall.

Mariposa.

THE TINGLE TAN MINE.—Mariposa *News*, March 23: If half the reports are true about the recent strike on Bear creek, G. C. Myers and C. A. Schlageter have struck a good-sized bonanza. It is about a half-mile from the old Mexican mine and nearly the same distance from the Feliciana. The samples of rock brought in by different parties have been estimated to go from $50 to $200 a ton, and there is lots of it in sight. A gang of men are now at work running a tunnel so as to strike the pay chute some distance below the surface. Mr. Rattry was over from Cathey's valley Wednesday. He reports a good pay chute in the old Kendall mine, now being worked by him and Mr. Anderson. The 10-stamp mill at the Bondurant was running short of water previous to the storm. It can now keep running till late in the summer.

HITE.—The Hite mine started up a few days last week, by the men. They were to run it and thus try to get their wages. It was shut down again, however, by order of Judge Walker. His lease has been extended to July 1st. Negotiations are now pending for its sale. This is why it was closed down so quickly.

DARRAH.—Mariposa *News*, March 16: Geo. S. Holeman is working his mine here. He expects to make a strike soon. The Vanderbilt mine made a cleanup last week of $2000 on a 20-days' run; this was quite satisfactory to McDonald. If the rock will pay that well right along he would run the property, without a doubt, on a larger scale.

PINE TREE.—The construction of the ditch and laying of pipe for the air compressors at the Pine Tree mine has been completed.

Nevada.

A PROMISING MINE.—Grass Valley *Tidings*, March 26: A quartz stringer showing coarse gold freely was cut on Monday in an excavation being made for a bob-pit on the Roach & Manion claim, Deer Creek, back of Greenwood cemetery. The claim has been worked for years by horse-power, but with depth and an increase of water in the mine, machinery is now imperative. W. C. D. Body, the well-known millwright, is engaged in placing the Rising Sun (Willow valley) pumping and hoisting plant on the mine, and calculates on completing the job within a fortnight. One thousand feet of pipe is to be laid from the Excelsior ditch to the mine, where water-wheels are to be put in and the machinery operated by water-power. Although the ledge of the Roach & Manion mine is not large, it is in good working ground and is rich, crushings yielding from $50 to $130 a load. There are many rich stringers in the locality, and Mr. Body and other gentlemen are confident that the development of these will add to Grass Valley's resources another group of mines.

BRIEFS.—On Monday the pumps at the Coe will be started up and the mine cleared of water and cleaned up for inspection. Capt. White is managing the property and has appointed Marshal Reynolds, who is one of our best miners, as his foreman. When the water is "forked," the Denver (Col.) bondee, Mr. Craig, will thoroughly inspect the property and determine whether to proceed with development work. Rumors of a settlement with the attaching creditors of the Green Mountain Con. Co. were bruited about the streets to-day. The mine is owned by a poor but enterprising company, a fact that should act as a buffer to any attempt to crowd it to the wall. The reported continued improvement of the ore of the Metropolitan mine, near Moore's Flat, was confirmed to-day by the receipt in this city of a small box of the quartz. The ore has a lively appearance, showing many coarse "colors," lead and sulphurets. The vein is a two-foot one and in favorable ground.

NEW YORK HILL MINE.—Grass Valley *Union*, March 21: The sale of a controlling interest in the New York Hill mine has been consummated by a deposit of the money to the account of the stockholders who placed their shares in the agency of the Citizens' Bank some weeks ago. The purchasers are understood to be James D. Hague and W. B. Bourn. It has been the supposition that the purchase was made on behalf of the North Star Co., but this is an error, Messrs. Hague and Bourn being the individual purchasers, although they are also largely interested in the North Star. At present there is a steam plant on the mine. This will be replaced or supplemented by water-power taken from the North Star pipe line which passes within a short distance of the main working shaft of the mine, and could be introduced at quite a moderate cost. The mine has paid a number of dividends and is right in the middle of the rich belt of quartz veins on the west side of Wolf Creek which has produced millions of value in gold bullion.

Placer.

CLEANUP.—Placer *Republican*, March 21: A cleanup is made at the Mayflower mine every two weeks. Last week the result was about $31,000, and the preceding cleanup yielded $52,000.

SMALL PIECES. — Several small pieces of gold have been picked up in the streets during the recent rains. The other day J. B. Chamberlin found a three-dollar nugget on the road down from his house.

Shasta.

PAUL PULVERIZER.—Shasta *Democrat*, March 20: The Calumet company is adding a Paul pulverizer to their already large plant. It is shaped like a barrel, revolves on axles, and pulverizes ore dry. It is said to be an excellent dry crusher. A landslide, caused by the heavy rain last week, covered up a tunnel on the Riley mine on Squaw creek, burying out of sight the tool-house and a lot of tools. Lee Fader has between 30 and 40 men at work on the new road between Kennet and Squaw creek. A miner named Patterson last week sold the old Black Jack mine on Flat creek to a Mr. Carter for $1500. Patterson left this morning for the gold-fields in Lower California.

LOWER SPRINGS PROSPECTS.—Cor. Shasta *Democrat*, March 20: The placer and gulch mines have been worked over and over until we can almost say that the last nugget has been picked up; but you can still see the many quartz ledges cropping out from our low hills and mountain-tops. From what experience I have had in quartz mining I do believe this place contains mines that, when developed by capital, will be the leading ones in the State. The White Oak, owned by Mrs. S. H. White, is one of the oldest locations in our place. There has been a great deal of money taken out of the mine. Mr. White—a man over 70 years of age—can show you ore that he is taking out every day that would make a prospector's heart feel glad to find. The Bulkhead, discovered and located by J. E. Tiffin—who still owns three-fourths, Mrs. E. Penrose being owner of the other fourth—lies 1000 feet north of the White Oak, also running east and west, has been crosscut by a tunnel 50 feet below the surface, showing a well-defined ledge from three to four feet wide, porphyry and slate walls, and prospects in free gold from $10 to $30 per ton, the sulphurets being very rich. A shaft sunk 400 feet east, shows a ledge at the depth of 38 feet, ten wide, yielding mostly sulphurets that assay $25. Then comes the Gem, supposed to be an extension of the Bulkhead. The Gem was located about four weeks after Tiffin struck the Bulkhead by William Kennett. After taking out a $400 pocket, Kennett sold to the Muchmore brothers. They made the big strike—took out about $10,000—and sold it for $35,000 to Mr. Miller, the present owner. This is one of the richest mines, but is lying idle for the present. A little north of the Gem is Mr. Wm. Lucas' claim. This is an old location, and has been worked mostly on top for pockets, and a deal of coarse gold taken out. West of and beyond the Gem are the Grotefend and Frick claims. These are locations made after the Muchmore brothers made the big strike. Mr. Frick has some very rich ore and is going to grind it in a horse arastra. These mines I have spoken of are not more than two miles from Sacramento river, where machinery can be worked cheap with free water-power.

REDUCTION WORKS.—Redding *Free Press*, March 16: We learn that Charley Butters is making a grand success of his reduction works at Kennet. He is buying the tailings of the Central mine, which he is working at a profit. Mr. Butters has been to a great expense, but can now see his way clear to make money. There has been considerable talk relative to the success of the Walker Bros. at Old Diggings; but the fact still remains that gold is being constantly produced, and some 30 men receive their wages promptly.

WILL NOT PAY.—Shasta *Courier*, March 23: It is reported that the owners of the North Fork Cottonwood and Eagle creek ditch will turn the water back into their original channels, as it will not pay the ditch-owners to keep it up, since hydraulic mining has been stopped by a few spies, blackmailers, and Sawyer. The stoppage of water running in that ditch, or rather canal, will work more injury to gardeners, orchardists and farmers than all the hydraulic mining did a hundred times over.

Siskiyou.

RIVER MINING.—Yreka *Journal*, March 20: The Kanaka claim at Klamath river is to be opened this season by a company of Portuguese miners, who will commence putting in wingdams within a few weeks. A San Francisco company, who bonded the Swiss Bar claim on Klamath river, expects to commence work early next month. They intend working the same by a new method, in using steam engines for hoisting and pumping, besides drifting in place of making open cuts. Messrs Heckathorne & Wademan, who have pounded out considerable gold from their quartz in a mortar at Greenhorn creek, built an arastra lately, but have not water enough yet to run it. Greenhorn creek has never been so dry as during the past winter, but there may be a good supply yet, if we have plenty of spring showers. The late rainstorms have furnished considerable water on several of our mining streams, giving the miners a chance to work the dry diggings and perform some ground-sluicing.

QUARTZ.—In this county there are at least 140 stamps in use in the several quartz-mills several being worked by steam. In addition there are also several arastras for prospecting, to be followed by erection of mills just as soon as the existence of permanent ledges can be established. Many of the rich croppings discovered are only pockets, that indicate good paying ledges somewhere in the vicinity, if not directly where the discoveries are made.

Santa Barbara.

BEACH MINING.—Lompoc *Record*, March 16: Parties have been engaged in mining gold from the beach sand for eight miles below the mouth of the Santa Ynez river; they have made good wages by the simplest process, and we have been informed that there was employment there for a thousand men for years to come. J. C. Barnes, an experienced miner, visited the beach gold-field Tuesday last, and says there is no doubt that large quantities of gold are contained in the black-sand region along the beach. He estimates that 1000 colors were obtained in a single pan of washed sand. There is a probability that a company will be formed to mine on a large scale. An engine could do efficient work in raising ample water to sluice off 30 tons of sand per day, which at the lowest estimate would yield $300 in gold. If this is to be the result, there are millions of dollars in gold in the miles of black sand south of the Santa Ynez river. We look for a big rush to this new El Dorado as soon as 'tis known on the outside.

San Diego.

STONEWALL CLEANUP.—Julian *Sentinel*, March 23: Gold by the bucketful at the Stonewall. Could some of the Lower California boomers have seen the cleanup at the Stonewall mine this week they would stop prating about ounces. The amalgam filled two large zinc buckets, and was valued at $35,000. Stop your blowing about Lower California.

Trinity.

THE MINES OF NEW RIVER.—Redding *Free Press*, March 16: In conversation with a gentleman

from New River we learn that the weather in that region has been unusually open. About Jan. 10th there was a heavy fall of snow which went off gradually and is now nearly all gone. Water is scarce; there is not enough water for the quartz-mills as is required, and the placer miners are having a hard time. He says, however, everybody is at work, it being a very busy camp and has bright prospects before it. G. C. Narvis is opening up two claims which he owns, the Occident and Goodenough. On the former he exposed a good body of about $20 ore, while on the latter he struck free gold and sulphurets. Gus Gutzen, who owns an extension claim on the same ledge, called the Golden Gate, has developed a 16-inch vein bearing $30 rock. The Ridgeway, 600 feet distant on the line with same ledge, is in the hands of an English company, which is working 15 men getting out necessary timber and tunneling. A tunnel is being driven which is to be 700 feet long and will tap the ledge at a depth of 400 feet. It is the plan of the company to spend $25,000 in the development of the mine. J. S. Thompson is operating the Excelsior mine with a quartz-mill, and doing well. The Mountain Boomer, owned by Clements & Ladd, is being worked right along with good pay. The mine has been bonded for $60,000. The extension of the Ridgeway, called Hard Tack, run through 15 tons of rock and cleaned up $185 per ton.

Tulare.

DUNLAP.—*Visalia Times*, March 16: The shaft on the Ninety-nine mine at Dunlap postoffice is now down about 70 feet. The ore bed at this depth is four feet thick and assays from $40 to $70 per ton. A six-inch strata of very rich ore is now found alongside the regular vein, and gold is discernible in this with the naked eye. None of the rock from this narrow strata has been assayed as yet, but it has the appearance of being rich enough to assay up into the hundreds. The owners of the mine, who are residents of this city, feel much elated over the find.

NEVADA.

Flowery District.

A POOR MAN'S MINE.—Virginia *Chronicle*, March 18: A recent cleanup of five tons of ore from the Adriatic mine, in Flowery District, netted the lessees, Messrs. Shepard and Lees, about $1200 each. The ore is gold-bearing and the pay streak narrow, requiring about three months' labor to extract a batch of five or six tons, but the bullion yield returns the lessees a handsome profit for their toil. The streak from which the pay ore is obtained resembles wall rock and had been passed by as worthless, for years, until the present experienced prospectors obtained a lease of the mine. The mine is worked through a winze below the main tunnel floor.

Hot Springs District.

EAGLE MINE IN CHURCHILL.—Reese River *Reveille*, March 21: J. N. Caldwell arrived here yesterday from Hot Springs mining district, and stopped at Triplett Springs to-day on his return. He tells us that with A. Woodworth, W. S. McCrackin and Thomas Canyon, as partners, he has been working on the mine for two years, and has now got it in good shape to work. It is called the Eagle mine, working it by a main tunnel 500 feet in length, and connected with a shaft 110 feet down, by making an upraise of 112 feet. By drifting 90 feet east from the tunnel they have cut a good-sized ledge, which will average $30 to $40 per ton in gold and silver, and at the bottoms the ore carries two-thirds gold. It is in a porphyry formation, and he claims that it resembles the ore at New Pass. They have a mill of five stamps, and collect the gold and silver by running it through a Howell improved amalgamating pan.

Jumbo District.

FAVORABLE.—Virginia *Chronicle*, March 20: The open winter has been very favorable for mining in Jumbo district. The Pandora and Wild Goose continue to yield the usual amount of gold bullion from ore worked in Six-Mile Canyon mills and Carson river arastras. Numerous locations in this district will be developed this year. The recent snow and rainfall is sending a heavy flow of water down the canyon on the Ophir grade road, and a string of sluices for placer mining have been set up in the ravine.

Kirman District

TO RESUME.—Virginia *Chronicle*, March 26: Operations in the Norrie mine, Kirman district, will be resumed next month. It is probable that a steam hoist plant will be substituted for the whim, with which a depth of 500 feet has been attained. Mr. Norrie, the divining-rod high priest, under whose direction the mine was located, is still sanguine that an important ore development will be made if the owners of the ground continue explorations. A majority of the locations made in the district three years ago have been abandoned.

Tuscarora District.

RICH SPECIMENS.—Reno *Gazette & Stockman*, March 21: At the Depot Hotel can be seen specimens of ore from a recent discovery in the Tuscarora mining district, which is hard to beat in any country. There are about 15 pounds of the ore, and Mr. Farrington of the Reno Reduction Works says it will average $40,000 to the ton, free gold being perceptible all over and through the specimens. Two men, George J. Smith and Hugh M. Kerr, are said to own the entire find, which they call the Eira.

BELLE ISLE.—*Times-Review*, March 22: West crosscut, 250-foot level, extended 15 feet, passing through about two feet of spar carrying a little iron.

GRAND PRIZE.—East drift, 300-foot level, extended 11 feet in a good width of high-grade ore; 400-foot level: West drift on the old vein extended 8 feet; face shows some improvement.

FOUND TREASURE.—Preparations are being made to sink the shaft 100 feet deeper, and to prospect the country—lately restored to us by the courts—which lies east of the east vein.

NORTH BELLE ISLE.—The stopes above the 300-foot level show an improvement in first-class ore. The stopes above the 150-foot level are yielding some very fine ore.

COMBINATION SHAFT.—The Combination shaft has been sunk and timbered 10 feet below the third station. The rock continues hard and shows some iron.

COMMONWEALTH.—225-foot level: South drift from No. 1 west crosscut has been advanced 11 feet. At the intersection of No. 1 winze from 150-foot level, the body of ore is developing fine, both north and south. Average assay from car samples $285 per ton.

NEVADA QUEEN.—The stopes are yielding good concentrating ore, and the concentrators are doing good work.

NAVAJO. — The stopes are without material change, and the usual quantity of ore has been sent to the mill.

Wolverine District.

CHROME IRON.—Virginia *Chronicle*, March 26: The chrome iron discovery made in Wolverine district last year is developing in importance. Assays of the ore resulted in the discovery that it carries a high percentage of gold and silver. The vein is about 40 feet wide and the ore is almost solid metal. On the opposite side of the ravine from where the chrome iron deposit was found, a vein of decomposed quartz, assaying high in gold, has been developed.

ARIZONA.

MOHAVE NOTES.—*Miner*, March 23: There are 18 men employed at the Copper World mines. The Rogers Bros. and Fisher have recently made a rich strike on the Smuggler, an extension of the C. O. D. They have worked for some time on the claim without any encouragement to speak of, and were about to give up when the strike was made. Rob't Steen and Geo. Koster left Saturday for Cedar district with a pack train of five mules loaded with mining supplies. A strike of high-grade ore has recently been made there and the indications are good for a good mine. The ledge is wide and easily worked. Considerable excitement has existed during the past ten days over the discovery of placer gold-fields at Carrizo, in Apache county, about 15 miles east of Holbrook. Fifty men left Gallup one day this week for the new fields. Every kind of conveyance is being put into service to carry passengers and freight from Holbrook to the placer-fields. By, and Wm. Sherman returned from Mountain Springs, Burro mountain, where they have been developing several copper claims this winter. They have an abundance of copper, but the distance from the railroad does not warrant their working at present. They spent a month working in the placer-fields in Yavapai county, and say it was an easy matter to make wages there. They will work on their claims in the Wallapais this summer.

DAKOTA.

LUCILLE.—Deadwood *Pioneer*, March 23: Howell Jenkins is prospecting for the upper contact. The Co. has a good small ledge of ore, and is seeking for the larger body.

RUBY BELL.—Silence at present prevails at the above favorite mine. The large quantities of high-grade ore in the old tunnel are too well known for mention here, but on the upper tunnel little is known. Considerable work is being done in the south part of Ruby. The Mountain Rose has a shaft to a depth of 106 feet; no water as yet and the indications are the most favorable.

RUBY BASIN.—Notwithstanding the reduction works catastrophe, a visit to Ruby Basin gives one pleasure in noticing the development and prospecting that is steadily being performed. At the Troy the drift from the bottom of the 50-foot shaft is being pushed toward the supposed ore body as per survey of Harmony vein.

IDAHO.

OPHIR MOUNTAIN.—Cœur d'Alene *Record*, March 17: In our Friday issue we made brief reference to the fact that on Wednesday last a body of ore of remarkable richness was struck in one of the tunnels of the mother lode. We referred to a small specimen of the ore which a *Record* reporter had in his possession, saying that the lowest estimate of its value was about $25 per pound. To-day we are able to speak from actual weights, which show that the piece in question which weighs 29 oz. 9 pwts., contains at least 10½ ounces gold, and is worth nearly or quite four times as much as the low guesses put it. We confidently expect to prove to our readers within a week that a single wheelbarrow load of the ore has turned out more than $5000. We know that there are plenty of pieces as good as the one we have tested, and we know that 50 pounds, such as it, would yield nearly if not quite $5000. As we have already said, it is impossible to foretell the extent of the pocket, as it is called, though there is nothing except the superior richness of a few feet of the vein to attract the notice of the casual, inexperienced observer. From the mouth of the tunnel up to the pocket, as we will continue to call it, which is about 180 feet distant, the ore vein carries pretty uniformly about $30 per ton. This is about the value of it both above and below a space of some ten to twelve feet in the center and upon the upper half of which is a pocket about 3x1½ feet on the face; the depth is not yet known. This is the fifth discovery of this kind made in Ophir hill, one at the foot, one at the top, and three between, suggesting the idea of convenient lodging stations along the white trail of the yellow incumbent of rock-ribbed mountains.

THE DESTINY OF CŒUR D'ALENE.—Wardner *News*, March 16: The manifest destiny of Cœur d'Alene is upward and onward. We are entering on a new and grand era of prosperity that will greatly accelerate the development of our mines and do much toward increasing the deep interest taken throughout the country in all portions of our mineral domain. Nature has done much for this favored region, and man is doing his share in return. The work is progressing bravely, and at every point, from our most accessible valleys to our almost inaccessible summits, the prospector is employed, the miner is delving deep into the mountains, and the wonders of this wonderland are being brought to light. In this age of advancement when the rich and poor alike strive to keep pace with the progress of the day, there is no country on earth that offers so wide a field to both the moneyed and the laboring classes. To the former, if he possesses the faculty of keen observation, the opportunities offered here for increasing his wealth are unlimited. To the latter, the chances of rising from comparative penury to affluence are equally flattering, as many instances illustrating the fact can be found among us. Numbers of men who landed in Cœur d'Alene penniless have acquired a competence, while there are many of the same class who are now accounted wealthy and are on the straight road to become millionaires. These are the advantages that a mining country alone presents. That Cœur d'Alene possesses them in a greater degree than any other portion of the Northwest, none who have ever visited our mines will care to dispute.

LOWER CALIFORNIA.

THE GOLD MINES A FAILURE.—Cor. S. F. *Examiner*, March 28: The much-extolled placer diggings of Santa Clara are a failure, and the argonauts of 1889 will go down in history only as the victims of a glittering delusion. There is gold there, beyond a doubt, but it is scattered so thinly that it is costing much more than a dollar for every dollar's worth that is taken out. I was offered good claims in Mexican gulch, which is considered to be the richest of all, for from $20 to $100 each. On the road to the mines I met scores of gold-seekers returning. One of these, a Mexican who had a mine to sell, showed me a $17 nugget and a $5 nugget, which he assured me had been taken out of his claim. I also passed several unfortunates, each of whom had a roll of blankets and a coffee-pot strapped on his back, his blistered feet being bound in gunny-sacks. One of these showed a $3 nugget and another about $4 or $5 worth of gold in a pill-box. They were going back to the United States, cursing the country and all that was in it. The greater load of profanity was dumped upon the shoulders of the International Land Co. of Mexico, which, the victims declared, was responsible for the lies that had been told about the richness of the placers. Mexican gulch, or that part of it which is being worked for gold, is about three-quarters of a mile long, with a depth of from two to six feet. A ditch two feet wide by one foot deep runs through it, and into this ditch the water of the rainfall has been turned. At intervals of 40 or 50 feet holes six feet in diameter by about three feet in depth have been dug as reservoirs, in which the water used for cooking and drinking is allowed to settle. All the water used for general purposes comes from the watershed of the mountain sloping to the gulch, and in the absence of any more rain, it will be only a few weeks hence when mining will have to be suspended for lack of water. I estimated there were 250 men working in Mexican gulch and about 200 of them wanted to sell out. In Mexican gulch 120 placer claims, 65 feet square, have been taken up, and 56 quartz mines and extensions in that locality have been placed on record. American camp, which is a spur of Mexican gulch, was next visited. Here I counted about 150 tents, including the inevitable store and saloon. Between 100 and 150 miners are stopping here, but they have done but very little work in American canyon. A good stream of water which will last several weeks flows through the canyon, but it is not being utilized save by 40 or 50 miners, who have not washed the dirt to a greater depth than two or three feet. The new diggings, which are four miles by trail from Mexican gulch, are known as the Arroyo Alamos. They are in a bog of black sand and loam, part of a plateau which extends for several miles east and west and north and south. Directly west of the Alamos is a tall, rocky peak, separating the Arroyo Alamos from American and Mexican gulches. About 200 miners were working in the little stream with pan and rocker, with but indifferent success. Water for domestic purposes is obtained from holes dug two or three feet in the bog. Horses and burros graze here on a dry bunch grass that will barely sustain the life of the hard-worked animals. The placer mining here is attended with great difficulty, for the reason that the dirt has to be carried to the water to be washed. Near my tent, in which I write this dispatch, three men are shoveling dirt into a wagon to which four horses are attached. On the wagon-bed is spread a piece of canvas to keep the dirt from falling through the crevices. The horses are then driven through the miry ground to the stream 100 yards away, where the dirt is shoveled into a rocker and washed. This gang of five men in three days took out $16 worth of gold dust. A careful estimate gives 1200 as the number of men now on the ground. "There is something very peculiar about these diggings," said a miner. "I began washing dirt in my pan from the surface of the ground to the bedrock. The first three or four inches of soil consist of black sandy loam, and I could not get a color in that. The next few inches are a greenish-brown dirt, and here I got gold. From that to the bedrock I got nothing." "There is no bedrock here," said an old miner, working several yards above the claim of the last speaker. "It is, as you see, a blue clay or a slate. Most all the gold taken out of the Alamos diggings has been found a few inches from the surface." Other disappointed miners were loud in their assertions that the placers had been salted. "These fellows," said one, "who want to sell claims and leave the country, carry some gold-dust in their mouths, and when you step up to see how they are getting on, they slyly spit into the pan. Others will offer you a chance to try your luck. They will hand you a shovel and tell you to shovel some dirt into the pan. You accept the invitation, and when you have finished washing you will find a $3 or $4 nugget." Everywhere I went I heard the same story of misrepresentation and blighted hopes. The boom is indeed dead. They came with buoyant hearts and new shoes, heedless of the fields of clover through which they passed, or of the bowlders in the road over which they stumbled. They returned with their blistered feet tied up in gunny-sacks damning the country. Ten tents were struck in the Alamos to-day, and as many wagons took the homeward road. It will not be many weeks before the jackrabbit will vainly burrow for water in the prospect-holes of Mexican Gulch, and the slinking coyote will devour the last scraps of bacon-rind left there by the miners.

MONTANA.

THE APEX PROPERTIES.—*Inter-Mountain*, March 23: A deal was consummated in this city yesterday whereby the Apex properties will be still further developed. Some two weeks ago the ownership of the properties was transferred from John H. Shober and I. William Adams to the Climax Mining Company, and yesterday Mr. Adams came over from Helena and filed articles of incorporation of the latter company. The Climax Co. will be a close corporation. Its incorporators are John H. Shober, I. William Adams and Ed. Hicks. These are the gentlemen who two years ago bought the Apex properties from Wm. Burton in the interest of Kansas City parties, who failed to come up with the money. Legal complications then arose and the development, which had begun on a large scale, was stopped for a time. The properties were bought in at sheriff's sale by Shober and Adams, and for the past two years a force of six men has been prosecuting development work on the First Class claim. The properties consist of the First Class, Monument and Backbone, all on the same lead. The shaft on the First Class is now about 300 feet deep, and a large body of ore has been opened up. The Climax Co. will now erect a five-stamp mill on the property and has let a contract for the same to the Montana Iron Company of this city. This mill will be put up at once. The ore in the First Class carries both gold and silver from $40 to $60 per ton.

NEW MILL.—Phillipsburg *Mail*, March 14: The new Granite Mountain mill will not be put in operation for at least two weeks hence, owing to the non-completion of the tramway, which is the only way by which the ore can be conveyed rapidly enough from the mine to supply the mill.

NEW MEXICO.

NUGGETS.—Silver City *Enterprise*, March 23: Some very fine gold nuggets have been washed out by Mexicans at Cold Springs gulch, about half a mile from Hillsboro. The management of the Carlisle Mining Co. has received orders to sink the main working shaft 200 feet deeper. The Beck mine, at Stein's Pass, has been leased to John Craze of Tombstone. Hoisting works will be put up immediately. Rich silver prospects have been discovered about 30 miles south of Las Palomas, and if reports can be relied upon, must be very rich. The Flagler works are now prepared to purchase ores in small and large amounts, paying cash for the same. This is just what the prospector has needed for a long time. Bell & Stephens of Pinos Altos have just finished a test run of ore from the Ohio mine, which adjoins the Mountain Key on the south. It ran $15 per ton. The vein is 3½ feet at a depth of 112 feet, and still improves in width and value as depth is attained.

OREGON.

PLACER MINING.—Bedrock *Democrat*, March 20: The heavy rains of the past week give hopeful indications to the placer miner that the present mining season will prove more remunerative than was anticipated a few weeks ago. The snowfall of the past winter has been much lighter than usual, but the late rains indicate that while the showers have spread pretty generally over the valleys and range, in the mountains, from whence the source of water supply is obtained for mining, snow has fallen to a considerable depth. Mine-owners in various localities have taken advantage of the opportunity offered and have started or are preparing to start their claims, the more prominent of which are the placers of Sumpter, Granite, Robinsonville and Parkers. In these localities extensive operations are carried on scientifically, and during a favorable season the output of gold is large. At Sumpter, several claims are in operation, owned by both whites and Chinese. The claims of Archie Downie, probably the best-equipped with modern appliances in the camp, have commenced the season's work, and should the supply of water continue for a reasonable length of time, the yield from these claims will be immense. At Granite, placer mine-owners are preparing to commence the season's work. In the camps of Robinsonville and Parkers operations have commenced, and the outlook for a water supply is favorable. At Deer creek, the Deer Creek Mining Co., Dan Carn, superintendent, has started up and expects a good run. In other portions of Baker county some placer-mining operations will be carried on.

UTAH.

PARK CITY NOTES.—Cor. Salt Lake *Tribune* March 23: The past winter has witnessed a decided change throughout the district, from the steady, unchangeable movements of miners and mining men during the past ten years, or since the opening of the famous Ontario-Daly Company properties, yet the production of this one property alone is enough to thoroughly place the camp on a basis of established permanency. The discovery of the Woodside mine has also added considerably to the value and wealth of this district, and also established a fact that within a radius of three miles around Park City are prospects fully as valuable as the old producers, and all that is necessary is energetic mining and capital, to more than double its present output and value. Already this needed energy and spirit is being shown by the prospectors and mine-owners. The consequence has been that newer and better ground is being opened, not only in the Woodside locality, but in every direction from the camp. It is a most interesting and wonderful sight to even an old-time miner to witness the development-work, mechanical skill and systematic operations connected with the Ontario property. The heavy and costly machinery underground—that would puzzle an old-time mining man as to how they managed to get it down the shaft to a depth of 600 feet—is a remarkable study. Then, again, if you wish to see all the ground opened up in the Ontario-Daly, you would be compelled to travel a distance of 31 miles underground. There is estimated to be enough ore in sight to keep the two mills in continual operation for the next 20 years, and enough ground opened to keep 800 men employed there. The recent developments made on Woodside hill have given Park City a new and brighter impetus, and its people are awake to the encouraging opportunities now before them for money-making and proving the value of their camp. Ore is being uncovered on all sides of the hill, and leasers are engaging every opportunity to secure leases on every available piece of ground. The recent discovery made in the Creole property, situated within the city limits, has fully illustrated the fact that the entire hill is thoroughly mineralized. Ground is being opened for a mile along the hillside between town and the Woodside mine. The same class of ore as is being shipped from the Woodside at great profit has been found in the North Pole claim. The country is a perfect network of locations, and every prospector and miner is confident that with pluck and muscle he will find his fortune.

MECHANICAL PROGRESS.

Heating of Journals.

Journals and bearings heat from various causes: First, from lack of proper lubrication, this being the case with all kinds and under all kinds of conditions; a cause, however, that is easily remedied. But there are some causes that require some special study, and are not yet fully understood. One of the most important of these causes is that the materials in contact are of uneven texture. This is a cause which may not at first be apparent. A third cause which may exist independent of each of the first two mentioned is that the bearing surfaces are not properly fitted. As a variation of this may be stated a further cause, that the contacting surfaces, or, rather those surfaces which ought to be contacting, are not properly centered in line.

Let us consider the case of shaft journals made of puddled iron. From the very nature of this material, which is never homogeneous, but has a fiber more or less regular, caused by the presence of cinder or slag, such journals are difficult to keep cool under heavy pressure and high speed. We may turn, fit and center such journals with all possible accuracy, and when we put too much power upon them they will expand out of shape and cause heating. This trouble does not show itself with journals of cast steel or of any other homogeneous metal.

Still, as most of our journals are made of wrought iron and will continue to be so made, we must devise some method of doing the best we can with them. About the best way is to give them soft metal bearings, which will accommodate itself to the roughness and other irregularities of the journal. There is, however, one great objection to this, that once such boxes do heat, the babbitt will be apt to be melted and to run out of the boxes. It is very difficult to get a bearing metal soft enough to bed itself well to the journal and have other than a very low melting point. The disadvantage of brass for boxes (by brass I mean any compound of zinc and copper) is that it is seldom even in texture. For such cases, where a material is desired that possesses resistance to wear, while bedding itself well to the journal and giving no trouble from melting, raw hide may be strongly recommended. The steps of drill presses are run on raw hide. Phosphor bronze is about the only alloy of copper that is homogeneous.

It would be impossible to get any metal that would not become heated under great pressure and high journal speed; but when we take cast-steel journals and phosphor bronze boxes, we have two about as homogeneous bodies as it is possible to get, and the journal is the one that wears the least—as should be the case.

The heating of journals will of course follow a law; but the trouble is that so far there have not been enough experiments to enable us to apply this law through a full range of subjects. In framing a law and regulating our practice, there are three principal things to be considered: the power transmitted through and borne by the journal; the area of contact in the journal; that is, its diameter multiplied by its length, supposing it to be properly fitted, and the nature of the materials used for the journal, the box, and the lubricant. The power will, of course, depend directly upon the speed.

The greater the contact area of the journal, the less liable it should be to heat. In actual practice this is only so within certain limits, because in very long journals, if there be a crank upon one side, and the boxes are rigid, there will often be more heating than if the bearings are only 1½ journal diameters in length.

The reason that new journals, especially those of steam engines, are apt to run hot at first, is that the entire load comes upon certain very small areas of the bearing surfaces, and these heat. There are some cases where it is not well to have soft metal—as, for instance, where there is grit liable to get in between the contacting surfaces. If the bearing is of soft metal, the grit will get imbedded in it and form a "lap," cutting the journal away most thoroughly.

Circular-saw arbors, millstone spindles, and turbine steps are particularly liable to heat; the first because of the very high speed (from 750 to 1500 revolutions) and the second by reason of the heavy weight upon the bearing (about a ton in some stones). In the third, the weight of the wheel, shaft, etc., is sometimes supplemented by the downward pressure of the water.

Some makers recommend hard bearings for lathe spindles, and others soft; and perhaps both are right, but not always or entirely right. Where the frame of the lathe is very stiff and heavy, then the boxes should be as hard as they can be got. But if too heavy work be put upon a lathe with hard boxes, there will be trouble.

For heavy bearings, that is, for bearings that have a very heavy pressure upon them, which would squeeze out any ordinary lubricating oil, the best thing to use is graphite, either alone or in combination with oil or tallow. It has the property of filling up the roughness which has been formed, and cannot be squeezed out from between surfaces which are tightly pressed together. It has this disadvantage, that it cannot be combined with oil in such a way that it will flow readily and not settle in the bottom of the oil-cup.—*Cincinnati Artisan.*

WHAT TWENTY THOUSAND HORSE-POWER MEANS.—The London *Engineer* explains what 20,000-horse power means: It is more than probable that the White Star boats being built by Messrs. Harland & Woolf will develop 20,000-horse power. It is asserted that they will have each 12 boilers and 72 furnaces, worked with forced draught on Howden's system. Assuming that the engines will require 18 pounds of steam per horse per hour, then 160 tons of feed-water must be pumped into the boilers every hour. In 24 hours the feed-water will amount to 3840 tons. A tank measuring 52 feet on the side would hold one day's consumption, or it would fill a length of 493 feet of a canal 40 feet wide and 7 feet deep. Taking the condensing water at 30 times the feed-water, it will amount to 115,200 tons in 24 hours; or, for a six days' run across the Atlantic, to not less than 691,200 tons. This would fill a cubical tank 295 feet on the side—a tank into which the biggest church in London, steeple and all, could be put and covered up. The coal consumed will be 400 tons per day. This will require for its combustion 8600 tons of air, occupying a space of 222,336,000 cubic feet. It is impossible for the mind to take in the significance of these latter figures. It may help if we say that, if this air was supplied to the ship through a pipe 20 feet in diameter, the air would traverse that pipe at the rate of about 5 6 miles per hour. It will be seen that the circulating pumps and fan engines of such a ship have no sinecure.

AMERICAN SWORDS, BAYONETS AND CARTRIDGES.—According to the *Iron Trade Circular*, the *Times of India* publishes a statement by a military expert condemning the swords and bayonets of the Bombay army as unfit for service. The bayonets were lately tested, and the proportion of those rejected varied from 20 to 40 per cent. England lost the control of the Soudan through declining to use American copper cartridge cases. She has now adopted them. After she has lost some other country she will come to us for swords and bayonets. To use the words of the *Iron and Steel Trades Journal*: "In the days when Great Britain was the world's workshop the cyclical economic movements were more limited in their influence," or, in other words, England could then see that no other nation had better arms than herself. It is different now. Other nations keep shop, and sell a better article than the habits acquired in "the old monopoly days" allow her to manufacture.

A RECORD HARD TO BEAT.—In 1866 a Corliss engine was placed in the machine-shop of the Union Pacific railroad at Sacramento, Cal. The engine has a four-foot stroke and an 18-foot belt-wheel, and it has been run continuously since it was placed there, frequently running night and day, often until 10 o'clock at night. Up to this date scarcely $100 have been spent for repairs. Allowing but ten hours a day and 300 working days to a year, this engine has been working 66,000 hours, at the smallest calculation, since it was placed in motion. The belt wheel makes 70 revolutions per minute, and for the 66,000 hours it has been going has made 277,200,000 revolutions. The circumference of the belt-wheel is 56½ feet, and in making the 277,200,000 revolutions has traveled a distance of 2,964,354 miles, equivalent to more than 100 times around the earth. The belt-wheel has traveled at the rate of 45 miles per hour.

THE GRIP OF BELTS.—Experiments with a new eight-inch three-ply rubber belt upon new turned cast-iron pulleys, of diameters of 18, 24 and 36 inches, show that with 195 pounds tension and 90° arc of contact, the surface of contact being as 100, 133⅓ and 200, the grips were as 100, 105 and 147. With 180° contact and 195 pounds tension, the proportions of grip were 100, 114 and 172, while with 400 pounds tension they were as 100, 130 and 193; but these are only proportional. The proportional figures here introduced are to show that the greater the tension the less the influence of the pulley diameter with 90 degrees contact. This will, perhaps, go to show that the amount of tension to give a belt should depend upon the arc of contact.

THE METALLIZATION OF WOOD.—The process of imparting to wood some of the special characteristics of metal has become of considerable industrial value in Germany, the wood surface by this treatment becoming so hard and smooth as to be susceptible of a high polish, and, on being subjected to a burnisher of glass or porcelain, the appearance of the wood is in every respect that of polished metal, having, in fact, the semblance of a polished mirror, but with this peculiar and advantageous difference, namely, that, unlike metal, it is unaffected by moisture.

TO CUT A HOLE IN HARD STEEL.—A writer in an exchange says: Sometimes I have had to make holes in steel that was too hard to cut or file easily. Then I make a chemical mixture that will cut a hole. I mix one ounce of sulphate of copper, a quarter of an ounce of alum, half a teaspoonful of powdered salt, a gill of vinegar and 20 drops of nitric acid. This will cut a hole in any steel, or, if washed off quickly it will give a beautiful frosted appearance to the metal.

AMERICAN CARBONS.—It is said that American carbons burn longer than those made in Europe, but do not burn so steadily.

SCIENTIFIC PROGRESS.

The Canals of Mars.

A writer in a recent number of *Science* collates a number of facts in relation to the canals of Mars, so called, through which he gives us a very fair idea of the physical aspect of the little planet. Speaking of the canals, he says: "According to the observations of Schiaparelli, they lie in the torrid and warmer portions of the temperate zone, and extend from the Northern to the Southern ocean. They are in general 2000 or 3000 miles in length by from 30 to 150 miles in breadth. They are generally arranged in pairs 200 or 300 miles apart, and so exactly parallel that usually no deviation can be detected. They cut up the continent surface so that there is no spot more than 400 miles distant from one of these markings." If these canals are artificial, it may be asked, what is the use of making them so wide, and why should they be built in parallel courses? The late Prof. Proctor suggested that the canals are the diffraction images of rivers, produced by mists which hang over the river-beds. M. Fizeau suggests that they may be cracks between the masses of ice, and others still imagine they are strips of vegetation, the rest of the planet being bare. The canals are there, for many independent observers have seen them.

Considerable interest has been manifested to learn what the eyes that are looking through the great telescope at the Lick Observatory, in this State, have seen. It is confidently believed that revelations never before vouchsafed to man have been or may be revealed by the aid of that powerful instrument—that interesting facts in regard to our near celestial neighbor might be discovered and made known to the people of the State whose munificence has called this important instrument into existence, but thus far only little has been heard from it—in fact whatever has been noticed has been mostly given to the Eastern public or transmitted to European societies and journals. If nothing new has been or can be discovered, why not let the public know it, and why not let publication be made in the city where the noble founder of that observatory made his fortune and dedicated a large portion of it to the special purpose to which we refer?

Meteorological Lecture.

At a recent lecture given in Cincinnati on the above subject, Lieut. John C. Walshe, Chief of the Signal Corps, entertained a large audience for about two hours. The *World's Progress*, published in that city, says the lieutenant took the weather map as his subject, and from it proceeded to show that modern science had nullified the biblical assertion which says: "The wind bloweth where it listeth and ye hear the sound thereof; but whence it cometh and whither it goeth, ye know not." He told of the great general eastward drift of the atmosphere of the United States, how storms come either upward from the warm regions of the Gulf, or else entering the country from Western Canada blow southeasterly; how the general drift catches them in its embrace and draws them eastwardly over the Ohio valley and the great lakes and so out over the St. Lawrence valley to the Atlantic. He explained that the eastern side of these storms is warm and moist, because on that side is the upward drift from the Gulf of Mexico—warm and moisture laden, while the western side is cold and dry, because on that side is the cold and dry air from the barren shores of Labrador. He showed the mighty effect of the lofty barrier of the Rocky mountains upon our climate. He graphically and interestingly explained the construction of the weather map and illustrated how easily and simply predictions can be made from its systematized data. He showed how the errors in predictions arise from the fact that the Signal Service has as yet no facilities for getting at meteorological conditions outside the United States, whence the storms come, or in the upper atmosphere, where the conditions are widely different from those prevailing near the surface and are liable to affect them at any time.

SOUND UNDER WATER.—Recent experiments made by the French Government with the newly devised instrument called the hydrophone gave the following results: The sound of a bell weighing 300 pounds, which was struck under water, was heard at the greatest distance permitted by the configuration of the bay, namely, 5200 meters (3¼ miles). Excellent results were obtained on board a boat in motion, the bell being distinctly heard 1400 meters off, as well as the noise of the screw of the tug on board which the sounding instruments were placed.

MODES OF WRITING.—The various modes of writing that have existed since the human race began are both unique and amusing. The earliest method known was writing on bricks, tables of stone, ivory, and the bark and leaves of trees. There are several copies of the Bible extant written on palm leaves, hence the name leaf, of a book, referring to a tree, was derived. The Babylonians made their contracts of business on tiles or broken pots. The treaties between the Romans, Spartans and the Jews were written on brass. The speech of Claudius, engraved on a plate of bronze, is preserved in the Town Hall at Lyons in France. There are wooden manuscripts which must have existed prior to 1423. In the shepherd state people wrote with horns and awls, then they invented an iron bodkin. After that the stylus came into use, made sharp at one end to write with and blunt and broad at the other for effacing and correcting.

GENIUS, CAPITAL, MONEY, SKILL, BUSINESS, LABOR, FOOLISHNESS.—Tennyson, says a thoughtful writer, can take a worthless sheet of paper, and by writing a poem on it make it worth $5000. That's genius. Mr. Vanderbilt can write fewer words on a similar sheet and make it worth $50,000,000. That's capital. The United States Government can take an ounce and a quarter of gold and stamp upon it an "eagle bird" and "Twenty Dollars." That's money. The mechanic can take material worth $50 and make it into a watch worth $100. That's skill. The merchant can take an article worth 25 cents and sell it to you for $1. That's business. A lady can purchase a comfortable bonnet for $10, but prefers to pay $100 for one. That's foolishness. The ditch-digger works ten hours a day and shovels out three or four tons of earth for $1. That's labor.

AN ALLEGED NEW AND VALUABLE LITHOGRAPHIC PROCESS.—If what is stated in a French journal, *L'Imprimerie*, is true, M. Joseph Eberle, of Vienna, Austria, has discovered a method which is likely to transform the lithographic art, viz., that the principal advantages of the new process may be thus summarized: Drawings on stone will resist the strongest acids; the impression of crayon or pen and ink drawings is equal to the originals; long numbers do not affect the drawings; bad paper does not interfere with the beauty of impression; corrections can be done with the greatest facility; printing on dry paper is simplified, and it is easy to print machine, crayon and pen drawings, united in the same engravings; powdering is avoided, and in chromo work the colors preserve a sharpness of tone hitherto unattained.

THE EBB AND FLOW OF CIVILIZATION.—The covered reservoirs of Carthage, dating back fully 2000 years, are being restored by the Gas and Water Co. of Tunis. These reservoirs cover a space of 420 by 89½ feet, and are divided into 18 communicating compartments. They have been used several times before in widely separated periods. They were in full working order in the time of Hannibal, were again repaired under the Emperor Hadrian, and have been entirely neglected since the irruption of the Arabs, in A. D. 697, until the present French company took them in hand again. From the description given in *Le Genie Civil*, it would appear that the French engineers are practically reviving the plans of the original Carthagenian engineers; a remarkable instance of the ebb and flow of civilization in this ancient corner of our historical world.

A STETHO-TELEPHONE.—A Chicago inventor is reported to have developed what he cal's a stetho-telephone, which is a combined receiver and transmitter. A hollow extension about four inches long is attached to the receiver, from the end of which a small button protrudes slightly. This button is placed against the throat near the vocal cords, and the receiver is held against the ear in the usual manner. When the operator speaks, the vibrations of the throat are transmitted with, it is said, distinct clearness. The instrument is operated by the muscular vibrations that accompany the utterance of words. The device is the result of ten years of labor and is reported to have worked satisfactorily between Chicago and Milwaukee.

ALBO CARBON.—Those who have heard of "albo-carbon" as an element in house-lighting, and are not acquainted with its character, may be pleased to learn that "it is simply gas-light enriched by fine carbon." Of course there is a mechanical attachment requisite for its complete operation, but it is claimed for it that it reduces the cost of gas one-half, while the light is greatly improved. It is said to possess brilliancy and promote economy.

POWERFUL ELECTRIC LIGHTS.—The electrical search lights, with which every modern man-of-war is now provided, are in themselves articles of peculiar interest. They are of the arc pattern, ranging from 8000 to 30,000 candle-power, so arranged with reflectors that their rays can be concentrated into a single beam and thrown in any direction. An object two miles distant is easily illuminated.—*Electric Review.*

A BEAUTIFUL EXPERIMENT.—In the mechanical production of ice, freezing may be caused to take place so gently that a spray of roses may be put into a tank of water and frozen into the mass of ice without stirring a petal from its place. There it lies imbedded in all its beauty of form and color, as long as the ice can be kept from melting.

A NEW COMPASS or method of determining the true north by the use of electricity, but without the aid of the magnetic needle, is announced by the London *Electrician*. This will be welcome news to the sailing-masters of iron and steel ships, where the variation of the needle is often erratic.

USEFUL INFORMATION.

How to Model in Clay.

An outfit of five pounds of clay, a sharp jack-knife and one tool will do many wonders. This tool is made out of a piece of maple eight inches long; one end made flat about one-half inch wide, from the center gradually becoming thinner, until it is as thin as a knife blade. From the middle, slope down to the other end; hollow out the center, then sandpaper until perfectly smooth.

If the clay is not used immediately after purchasing, put it in any sort of a dish and cover with a wet woolen rag, keeping the rag wet.

Now for the work. It is better to buy a plaster slab, which costs only 10 or 15 cents at any pottery, although this is not necessary, as a common board or marble slab will do. In the first place make a tile six by four inches, and about one inch thick, by kneading the clay until all lumps are worked out; then throw it on the slab to make the clay more compact. With a rolling-pin roll until a little thicker than required.

If there should happen to be bubbles in the clay, prick them with a pin. Fill up the holes and make the tile smooth by rubbing it with moistened fingers. Turn it over and repeat the operation. If it is now thicker than required, smooth it down, and with the jack-knife cut it to the proper length and width.

Take a leaf for a model, for it is better to work right from nature; make an exact drawing of it, outline and veins, with the curved end of the tool. If the drawing cannot be done, a tracing may be substituted. Take the other end of the tool and cut this outline one-half inch deep, and then with a jack-knife cut away the clay outside the leaf, smoothing down the new surface.

Make the depressions in the clay leaf as in the real one. Sometimes the finger will be sufficient; sometimes the curved end of the tool will be necessary. There will always be some finishing touches to add, which the worker must see for himself.

When it is nearly dry, put in a background by simply rubbing the curved end of the tool over it in strokes. If the leaf proves a success, take it to a pottery, where for a few cents it can be fired. Otherwise it will crack and crumble away. If the leaf is unsuccessful, the clay can be worked over and used again.

After a leaf or two have been made satisfactory you can model flowers, or make something useful as well as ornamental, such as match-boxes, ash-receivers, and thermometer-holders, and perhaps, after practice, you will be able to model figures.

HOW TO SELECT ROPE.—A German paper, in an article on the present methods of rope manufacture from hemp, and the determination of the different qualities and the probable strength simply from the appearance, lays down the following rules: A good hemp rope is hard but pliant, yellowish or greenish gray in color, with a certain silvery or pearly luster. A dark or blackish color indicates that the hemp has suffered from fermentation in the process of curing, and brown spots show that the rope was spun while the fibers were damp, and is consequently weak and soft in those places. Again, sometimes a rope is made with inferior hemp on the inside, covered with yarns of good material—a fraud, however, which may be detected by dissecting a portion of the rope, or, in practical hands, by its behavior in use; other inferior ropes are made with short fibers, or with strands of unequal strength or unevenly spun—the rope in the first case appearing woolly, on account of the number of ends of fibers projecting, and, in the latter case, the irregularity of manufacture is evident on inspection by any good judge.

CALIFORNIA LICORICE.—There are fine growths of the licorice plant in several parts of California, but one of the best is near Madison, Yolo county. The Woodland *Democrat* says that the culture is extremely easy and the root is very profitable. Licorice is propagated like horseradish by means of root slips, which are removed from the main root. The soil must be well fertilized and thoroughly broken to the depth of three feet to attain the best results. It takes three or four years to perfect the roots for market, during which time the plant must receive constant and careful cultivation with the prong hoe. Lay off the rows two feet apart, and, after cutting the root slips into sections of five or six inches, plant them in vertical holes made with a dibble 16 inches apart, observing to thrust them several inches below the surface and cover over.

A NEW INDUSTRY has lately sprung up in Chicago—a railway seat manufactory. The seats turned out are novel in construction. They are double, each being operated separately, and made to face the front or back of the car by the simple pressure of a spring. The method is patented, and is the invention of E. N. Gilfillin and J. S. Emmert of Chicago. Fifteen roads have already adopted it, and the industry promises to very shortly assume considerable proportions.

A NEW STREET-SWEEPING MACHINE is on trial in New York City. The machine is a large circular water-tank, running on three wheels, underneath which are placed large rollers or scrapers set diagonally with pieces of rubber instead of bristles, as at present used in street sweeping. Under the driver's feet is a water-pipe, from which copious jets of water are thrown, washing away the sand, which is swept into the gutter and washed into the sewers. The machine cleaned two blocks in Fifth avenue, leaving the stone pavement as clean as it would appear on a summer's day. The time occupied was six minutes on each block.

DIFFERENCES IN DRAFT.—It is stated that if one horse can draw a certain load over a level road on iron rails it will take one and two-thirds horses to draw the same load on asphalt, three and one-third horses to draw it on the best Belgian block, five on the ordinary Belgian pavement, seven on good cobblestones, thirteen on bad cobblestones, twenty on an ordinary earth road and forty on a sandy road.

FRAUD IN PERFUMES.—A perfumer says that there is more downright fraud perpetrated in the manufacture of attar of roses than in the making of any other perfume. Connecticut is a prominent place of the production of attar of roses. Heliotrope, one of the most popular of perfumes, is made by combining violet and vanilla in certain proportions.

CALIFORNIA MAPLE SUGAR.—The sugar maple is found in various places in Central and Northern California. The Grass Valley *Tidings* recently acknowledged the receipt of maple sugar made from trees in Woodpecker ravine, east of the town.

A PENCIL GREASE for marking, which will keep soft the year round, is made by trying out some beef tallow and adding while warm a small proportion of sweet oil, say a teaspoonful of oil to a gill of the melted tallow. Keep it in a tin box.

OIL SURPLUS.—The oil-producers of Pennsylvania are encumbered with an accumulation of 3,500,000 barrels of the crude article, which they expect to sell eventually for less than $1 per barrel.

CRYOLITE for making candles is brought from Greenland, where important and little known mining operations are carried on.

SULPHUR IN LOWER CALIFORNIA.—The *Lower Californian* says there is sulphur enough on the peninsula to supply the world.

GOOD HEALTH.

Does the Sun Thicken the Human Skull?

One of the most interesting things mentioned by Prof. Virchow in his little book just published, entitled "Medical Remembrances of an Egyptian Journey," in which he describes an excursion up the Nile as far as the first cataract, is that the broken skulls on the first great sepulchral fields, dating from Roman times, are as thick and hard as Herodotus says those of the slain Egyptians were in comparison with the brittle ones of the Persians. The Greek historian explains this by attributing it to the early exposure of children to the heat of the sun; and in many parts of Upper Egypt the German travelers actually found young children thus exposed during their parents' absence in the fields in immense clay bowls, resembling in shape a champagne glass with a stem, into which they were put without shelter.

This discovery by Prof. Virchow is interesting, because it at once suggests the question whether the proverbial thickness of the skull of the negro has not been caused by exposure to the sun, and whether it is a peculiarity of savages of tropical countries that their skulls are thicker and harder than those of the inhabitants of temperate and colder countries. Students of craniology have never made any investigation to ascertain whether the skulls of different races vary in degrees of hardness.

It would be almost impossible to make such an inquiry. As is well known, the human skull increases in hardness from childhood to maturity and age. A miscellaneous collection of skulls of any given people would therefore be of no value in such an investigation. To obtain a collection of skulls of a number of nationalities, that should be taken from subjects of all the same age, to have them all similarly prepared and in sufficient numbers to make it possible to draw any conclusions from their comparison with each other, would be manifestly impossible. More attention has been given to the relative thickness of different skulls, or rather to their weight, from which their thickness may be inferred. Of the large collection of crania in the Army Medical Museum at Washington, the thickest are those of negroes and Alaskan Indians. The skulls of other Indians, both of North and South America, in tropical or temperate climes, and of the Esquimaux, do not appear to be particularly thick. Among the ancient Peruvian skulls recently received by the museum, and the ancient crania collected in Arizona last summer, there are frequent individual variations in thickness, but no tendency to unusual thickness.

The conclusion from these facts is that exposure to the sun probably does not cause thickness of the human skull. In connection with this subject, it is interesting to note that among the Australians the *sinus frontalis* is generally found to be solid in the males, instead of being hollow, as in the skulls of other races. This bone in the male Australians generally extends straight across the head, the lower side overhanging the eyes so that they seem to look out from under it, while in the North American Indians a modification of shape deprives them of that heavy look about the forehead. The heavy *sinus frontalis* of the Australians, of course, increases the weight of the skull.

WASH THE HANDS BEFORE EATING.—Children should be taught as we were taught when we were young, to wash the hands before sitting down to table. In coupling the injunction with the order to brush the hair and put on clean pinafores, we hide necessity behind propriety. The tousled locks and begrimed apron offend our eyes; the soiled fingers may work real evil to their owner. Dr. Cyrus Edson, in a lecture lately delivered, startles us by suggestions of the danger consequent upon neglect of this duty. The air we breathe, the dust we stir in the neatest apartment, the perfume we inhale, are alive. Tyndall says: "We find upon examination that dust is mainly organic matter, in part living, in part dead. There are among it particles of ground straw, torn rags, smoke, the pollen of flowers, the spores of fungi and the germs of other things." Teach the child, therefore, as soon as he can comprehend an order, to keep his hands away from his mouth, and never to touch a bit of food until they have been washed and dried.—*Marion Harland in the Home-Maker.*

TWO WAYS OF TREATMENT.—When a person gets a sprained ankle, the physician usually has the ankle painted with iodine and the patient kept in the house for a week or ten days. A physician who treats such an accident in a different way relates a case as follows: "I went over to a grocery store and got a pound of common soda. Then I got a pot of boiling water, put it in a tub and put the soda into it. Then I got some woolen rags, dipped them in the solution and wrapped them around the injured member. I wrapped dry cloths around on the outside, so that the steam could do its work thoroughly. I changed the bandages every 15 minutes and had his nurse do the same when I went home that night. When I called the next day my patient was all right. It would have taken two weeks for that iodine to have done its work. A peculiarity about this treatment is that no swelling remains and that the flesh is not even discolored."

CELERY AS A CURE.—Celery is the latest cure for rheumatism, says an Eastern exchange. It is asserted that the disease is impossible if the vegetable be freely eaten. The fact that it is so generally put on the table raw prevents its therapeutic powers from being known. The celery should be cut into bits, boiled in water until soft and the water drank by the patient. Put new milk, with a little flour and nutmeg, into a saucepan with the boiled celery, serve it warm, with pieces of toast, eat it with potatoes, and the painful ailment will soon yield. Such is the declaration of a physician who has again and again tried the experiment and with uniform success. He adds that cold or damp never produces but simply develops the disease, of which acid blood is the primary and sustaining cause, and that while the blood is alkaline there can be neither rheumatism nor gout.

A MEDICAL USE FOR THE PHONOGRAPH.—Dr. J. M. Bleyer, in a communication to the *Medical Record*, explains another use for the phonograph, to wit: teaching, recording, reproducing and demonstrating the physical signs or sounds of the normal as well as of the diseased condition of the heart and lungs. Like the great Lick telescope in astronomy, the phonograph in medicine has opened a new field of investigation. He says: "While the deepest tone that our ears are capable of recognizing is one containing 16 vibrations a second, the phonograph will record 10 vibrations or less, and can then raise the pitch until we hear a reproduction from them. Similarly, vibrations above the highest rate audible to the ear can be recorded on the phonograph, and then reproduced by lowering the pitch until we actually hear the record of those inaudible pulsations."

THE SOUL OF PHARMACOPŒIA.—The *Medical Record* prints the following list of drugs as representing the soul of pharmacopœia: Opium, mercury, iodides, quinine, chloroform, ether, sulphate of magnesia, salicylic acid, aloes, alcohol bromides, iron, chloral, castor oil, digitalis, arsenic, colchicum, ipecac, aconite, strychnia, cocaine, ergot, bicarbonate of potash, mineral acids, and nitrates. It adds: "Pepsin is a widely used remedy, but it can hardly be regarded as a drug, and it is very possible that, on the whole, it does more harm than good by pandering to a weakness rather than attacking its roots. Iron is another remedy whose value, except as a mineral food, is problematical. Naturally, the best 25 drugs will differ somewhat in accordance with climate and prevalent disease, but we should say that the foregoing list was a fairly correct one."

A MORNING DRAUGHT.—Add the beaten yolks of three eggs to two tablespoonfuls of powdered white sugar, three cloves, the rind of half a lemon and half a pint of brandy. Pour over it a quart of new warm milk, stirring rapidly, and serve immediately. This is recommended for those who live in malarial districts and for delicate persons.

A SALT SYNDICATE.—The formation of a salt trust now seems assured. The Michigan manufacturers met at East Saginaw, Mich., in secret and agreed to enter the combination. The idea is to cut down all works where fuel costs so much that there is only a narrow margin of profit, and the product of each district is to be regulated by the area it can control. The entire salt producing territory of the country is to be included. The trust is to have a capital of $25,000,000.

EX-MAYOR HEWITT and Edward Cooper, proprietors of the New Jersey Steel and Iron Works at Trenton, N. J., have been traveling in the iron regions of the South for several weeks on a tour of investigation. As a result, it is announced that about April 1st their works will be removed to Chattanooga, Tenn. Much of the raw iron and coal supply has been coming from there, and the company also have found a large market in that region. The works employ 1300 men.

MINING MUSEUM SPECIMENS.—Two fine specimens of the stone age have been put on exhibition at the State Mining Bureau museum. One is an ax found at the bottom of a Swiss lake, and the other is a diminutive hatchet from Chiapa, Mexico. Both are very fine specimens of ancient workmanship. There is also on exhibition a quantity of asbestos from San Bernardino county, and a perfectly smooth and symmetrical water-worn granite bowlder of egg shape from French Gulch.

FLOWERING PLANTS IN ARCTIC REGIONS.—Within the Antarctic circle there has never been found a flowering plant. In the Arctic region there are 762 kinds of flowers. Fifty of these are confined to the Arctic region. They are really Polar flowers. The colors of these Polar flowers are not as bright and varied as our own, most of them being white and yellow, as if borrowing these hardy hues from their snowy bergs and golden stars.

GARDNER F. WILLIAMS, who is in charge of the Kimberley diamond mines, Kimberley, South Africa, has recently, we are informed, had his salary raised to quite an important figure. Mrs. Williams and her daughter started from Oakland for Kimberley this week. Mr. Williams was formerly in charge of important gravel mines in California.

JAPANESE IN HAWAII.—The result of the extensive Japanese emigration to Hawaii has been to throw most of the Portuguese laborers out of employment, as they demand higher wages than the Japanese. About 2000 Portuguese are making arrangements to remove to the new State of Washington, if they can find suitable lands.

THE SILVER KING'S VICTORY.—The suits of the United States against the Silver King Mining Co., Arizona, for cutting timber on the public lands for mining purposes were tried at Phœnix before the United States Court recently. The jury found for the defendants. This is an important victory for the mining interests of Arizona.

THE Wheatland *Graphic* says a great many mining men and prospectors have visited Smartsville and vicinity of late, looking for mining investment. Kind fortune seems to be smiling on the town again, and old-timers who live in other places are casting longing glances at their old home.

THE amalgamation of the three great Chicago companies with $20,000,000 capital to make steel rails is now an accomplished fact, and will doubtless be greatly to the advantage of all the interests concerned, viz.: The North Chicago, the Union of Chicago and the Joliet of Joliet, Ills.

VESSELS' MASTS.—In many instances the captains themselves do not know the length of their masts to a few feet. One hundred and fifty feet is rather long, and there are probably 10 or 12 ships with masts coming to San Francisco whose length exceeds that.

GOV. WATERMAN has signed the bill providing for a commission of three engineers to make an investigation into the condition of the San Joaquin and Sacramento rivers, and has appointed William Ham Hall and P. A. Humbert as two of the commissioners.

THE Reese River *Reveille* says: Express Agent Crockett of Austin has footed up the bullion shipments from his office since 1885, and finds that they amounted to 1,707,704 pounds, of the value of $24,929,699.

IT is said that the smelters at Tacoma, Wash., will be ready for work May 1st. The statement that the parties who are building the smelter had changed their minds and would build at Portland is contradicted.

THE decayed remains of Walter Brown, a young Leadville miner, who has been missing since May 15, 1887, were found recently at the bottom of an old shaft of the Iron Silver mine, 125 feet deep.

A NEW SMELTER.—Portland's smelter and refiner is an assured fact, the company having purchased 110 acres several miles below town. The construction will begin immediately.

Passing Events.

The latest advices from the Lower California gold-fields bear out the prediction made weeks ago in the PRESS, that they are by no means extensive and there is lack of water to work them. A number of quartz veins have been discovered, but capital is necessary to work with. A great many disappointed people are now returning.

Greater interest than ever is being manifested in the oil-fields of the southern part of this State. Vigorous search is also being made for natural gas. Eastern people have sent experts out, who are investigating these subjects in Ventura and Los Angeles counties.

In Arizona the excitement concerning the Carizo gold-fields is unabated, though there is no reliable news as yet from the district. The Harqua Hala mines, which latterly attracted so much attention, but were finally considered mere rich pockets, are now reported as improving in width and quality of ore as depth is attained.

Railroad business in California is now quite dull, and the S. P. Co. are curtailing expenses by reducing the force of men. It is stated, however, that it is the intention of the company to build some 200 miles of feeders and branch lines on this coast during the summer.

The Los Angeles Base-Line.

Its Measurement by the U. S. Coast and Geodetic Survey.

The measurement of a base-line in any scheme of triangulation over the surface of a country is the first and most important operation, for upon it in great measure depends the accuracy of all subsequent measures of distances. The base-line is that one of the three sides of a triangle that has been selected for actual measurement. At the three angles of the triangle each horizontal angle is measured, and from these measures and the base the other two sides are computed.

When the network of the triangulation is intended to extend hundreds of miles in any, or all, directions from the base, it is very important that the base-line shall be measured with the best apparatus and the highest skill. In the operations of such work in Europe and India base-lines have been measured with glass rods, wooden rods, steel bars, composite bars of steel and brass, steel and zinc, etc. In our country, the first measures by Hassler were with steel bars, and that is the latest method in Europe, and has been urged by Davidson for years in this country.

The primary apparatus of the Coast Survey is a composite bar of parts of steel and zinc, so arranged that the length of the compound bar is nearly compensated for changes of temperature and has therefore a nearly invariable length. There are two such bars practically of identical length. In the later European measures there is only one bar which is carried under a series of microscopes fixed in line. The operation of the field measurement is, generally speaking, as follows:

After the rear end of the first bar has been adjusted over the end of the base-line, the second bar is placed ahead of the first one in the line of the base, and the rear end of the bar is moved back gently to touch the forward end of the first or rear bar. When this contact of the two bars is adjusted the rear bar is released and carried forward of the standing bar and then brought in contact as the first was.

Of course it is understood that the alignment of the bars is perfect, that the inclination of each bar is accurately measured, so as to give the means for reducing the inclined length to the horizontal equivalent, and that the hight of the base-bars above the level of the sea is known so as to reduce the length to what it would be at the mean level of the adjacent ocean.

The temperature of the bars is also noted by mercurial thermometers and the Borda scales are read to reduce the length of the bars to a standard temperature.

The length of the bar has been a matter of personal consideration. Hassler used four bars of two meters each to form one measure; Bache used two compound bars of six meters each; Patterson adopted the present one of five meters; the Spanish and Swiss authorities use a bar of four meters. Questions of strain when the bar rests upon two supports enter the problem, but the weight is the principal consideration. In the base-bars of the Coast Survey the weight has been increased to the maximum which two men can handle in the rather unusual method of lifting, carrying, and setting them in place in the shortest practical time.

The present bars weigh 160 pounds each, and each has to be changed to a new position every minute when the other conditions for work are favorable. From the experience gained on the Yolo base the bars have been so covered with non-conducting material that ordinary changes of the temperature reach the bars only after two or three hours. The amount of this material limited the weight.

In European and Indian base-lines, and in some of the base-lines heretofore measured in the United States, the surface of the ground has been either carefully prepared and graded, or the lines, when short, have been measured on highways of the best character. In the last two bases measured by the Coast Survey the land has not been prepared nor graded, and no hesitation has been made about crossing streams upon trestles properly constructed. In the modern base-lines of Europe the practice has been to measure a short base of about one and a half miles at least two times. This involves the intervention of many triangles and the measurement of many horizontal angles before lines of 40 and 100, and even 150 miles, are reached, as on the Pacific Coast triangulations. These intervening measures are sources of error through which the value of an accurately measured base-line is soon lost. In the Coast Survey, where the development of the main triangulation has reached lines nearly 200 miles in length, the bases have been chosen as long as practicable for the best geometrical figures developed therefrom. In the Yolo and Los Angeles base-lines these lengths have been ten and three-quarters miles and the extension therefrom to lines of 40, 60 and 100 miles has been systematic and through well-conditioned quadrilaterals. Moreover, it has been shown to be economical to remeasure even such a long base-line, because the second measure may be considered almost a new base, and is made in much less time than the first without the double preparation and has a greater value because the persons manipulating the instruments are then well practiced and alive to all field sources of error. Another check is made in all well-measured bases, by the introduction of subdivisions in the line upon which the tests are made in the second measurements. General Ibaanez adopts subdivisions of 400 meters in a mile and a half base-line. The Coast Survey introduces subdivisions of 500 meters in ten and three-quarters miles. In the base just measured by Professor Davidson's party it was determined to measure it three times, and he believes that the third measurement should have more weight than either of the others in making up the mean value. Moreover, the third measurement was measured in much less time than either of the others, and therefore more economically.

In four months' time, which involved going to and leaving the field, building ten bridges or trestles over streams, crossing two railroads, clearing the ground of great tussocks of hard, stiff grass, etc, the first measurement of the line of 17,496 meters occupied 21 working days, the second 14 days, and the third only 11¾ days. In the second measurement the greatest distance measured in one day was a trifle over one mile; in the third measurement distances were made of 1700, 1700 and 1810 meters on three consecutive days, and the extraordinary length of 2000 meters was measured in one working day of seven and a half working hours. In the later measurements in Europe (Aarberg base-line) the measurements are considered good with 800 meters in five hours.

In the day of the greatest measurement on the Los Angeles base the bars were measured at rates of 100 bars in 96½ minutes, 104 minutes and 101 minutes. In the Aarberg base the shortest time for 100 bars of four meters each was 189 minutes.

In the three measurements which comprised the laying of 16,497 bars, so well were officers and men versed in their duties that no accident and no mistake was made by any of the 20 persons employed in this rapid manipulation. The greatest inclination of any bar was within two minutes of five degrees; in the Aarberg base not quite two degrees.

The position of the Los Angeles base-line is between Anaheim and Norwalk, and the northwest end is about 15 miles from Los Angeles. The line is peculiarly strong in its geometrical relation with the long lines of the survey upon the adjacent mountains and coast hills. On each side it develops directly through a quadrilateral, and when the figure immediately around it is connected by horizontal angles, it will be remarkably strong, with good lines for the development to the north and south and to the Santa Barbara islands.

The choice of the base-line was made by Capt. Jas. S. Lawson in 1886, and the survey of the line and the adjacent land was made by Mr. E. F. Dickins, both then attached to the party of Prof. Davidson.

After the measurement of the line, the extraordinary rapidity with which it was measured was particularly satisfying to Supt. Thorn, who mentioned it among other services in recommending Prof. Davidson to the President's notice for appointment as delegate to the International Geodetic Association.

From comparison with the conditions in the measurement of the Yolo base-line, and from a test of three measures of one-half kilometer on this line, it is believed that the probable error of the length of the Los Angeles base-line will not exceed one-quarter of an inch. This base serves as a check upon the measures of the lines of the triangulation brought southward from the Yolo base; and will be the base for the development of the triangulation hence to the Mexican boundary and through the Santa Barbara islands.

New features were introduced in the measurement of the Yolo and Los Angeles bases by the daily comparison of the measuring bars with a field standard bar that is subsequently compared with the ultimate standard at Washington. In making these comparisons, the quantities read by the observer are the one-two-thousandth of a millimeter or about the one-fifty-thousandth of an inch. In these comparisons the actual field conditions of the measuring bars and the standard base are realized, and must give more reliable results than what may be called office comparisons.

Lower California Mines.

Numbers of men are returning from the Santa Clara mines, Lower California, disappointed in both the extent and richness of the field. Many still remain, of course, and will thoroughly prospect the country. The majority of those who went to the new fields were "tenderfeet," with no knowledge of mining; but in the crowd were many miners of experience who will give the region a pretty good examination. The Mexican miners, familiar with the kind of placer-mining work necessary in that region, have been the most successful, but there was by no means paying ground enough for even one-tenth of the people who went to the district. The reports of rich finds were much exaggerated. Some rich spots were found, but the area of the placers is limited. On the other hand, the quartz finds are reported as numerous and apparently promising. Quartz mines, however, generally require capital to develop, and most of the people who went down there had very little of this. Those who had the luck to get hold of good quartz claims will doubtless be able to sell them before long, but before the mines can pay much, money must be provided for reduction works.

General Luis E. Torres, Governor of Lower California, has sent the following message to Senor Valdespino, Mexican Consul at San Diego: "Please publish through the press of San Diego that the richness of the Santa Clara placers has been much exaggerated. None but practical miners (gambuzinos) find gold. Possibly new discoveries may be made, but to date the placers found do not justify the excitement that has been caused. The prospectors coming in may probably rely on new discoveries, but about this there is no certainty."

This is a very sensible message, but it is to be regretted that it was not sent some weeks since, as it would have prevented much disappointment. However, the Governor could scarcely have expected such a rush of people to his Territory on so slight encouragement.

We see by a dispatch from the City of Mexico that the Government has decided not to sell to one company all the mining concessions in Lower California. It is preferred that practical miners shall take up claims, and every effort will be made to induce miners to enter upon mining lands.

RIVER AND HARBOR COMMISSION.—Among important bills passed by the Legislature was one entitled an Act to provide for the appointment and operation of a River Examining Commission. It provides that the Governor shall appoint three Commissioners to report upon the condition of the Sacramento and San Joaquin rivers, with the view of informing our members of Congress as to the general appearance and estimates of cost of improving these rivers and restoring them to the condition in which they were before hydraulic mining had filled them up. When we went to press last week, but two of the Commissioners were appointed. Since then the Governor has completed the appointments. The Commissioners are Charles F. Reed of Yolo county, P. August Humbert and Wm. Ham. Hall.

Aid Your Publishers.

Now that general success for this season is so well assured, we hope to receive early remittances from old subscribers and to add many new ones to our list. We shall be grateful to present subscribers who will call the attention of new-comers, as well as any old neighbors, to the importance of reading our paper, and supporting a journal that does so much for its subscribers and the welfare of the whole community on this coast.

Hot-Ore Feeding Machine.

In order to charge the hot ore evenly by a mechanical contrivance, Mr. Hofmann, in carrying out his trough-lixiviation process, has devised an arrangement, which, in combination with a Howell roasting furnace, is illustrated in the accompanying cuts.

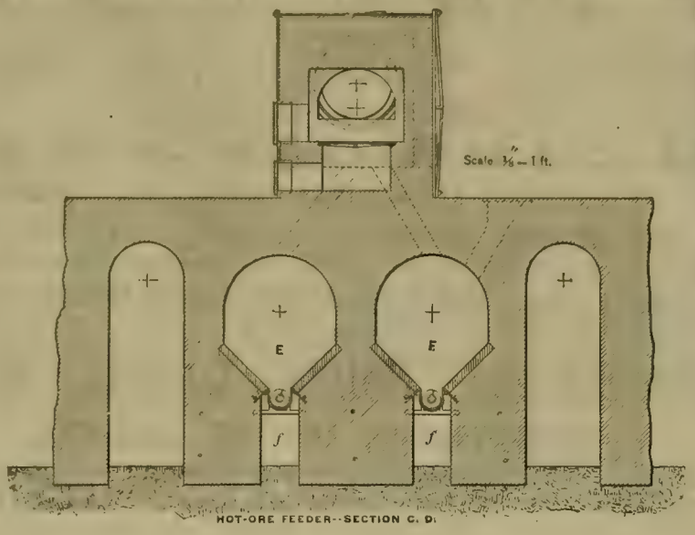
The ore from the furnace drops alternately into the bins or vaults *E* and *F*. The ore is recovered from the bins by conveyor screws. These, with the conveyor troughs, are placed below the inclination of the bins in order to keep them comparatively cool by the air in the channels *f*. The four-inch shaft of the conveyor, over which the cast-iron screw segments are slipped, consists of three pieces which are connected close in front of the journals by large flanges *g*, in such a way that the coupled ends do not touch each other. The object of these flanges is to keep the journals cool. For this purpose the vessel *h*, through which a small but continuous stream of water flows, is so placed that the flanges have to revolve through the water. The inflowing water strikes the upper half of the couplings to keep them also cool when not in motion.

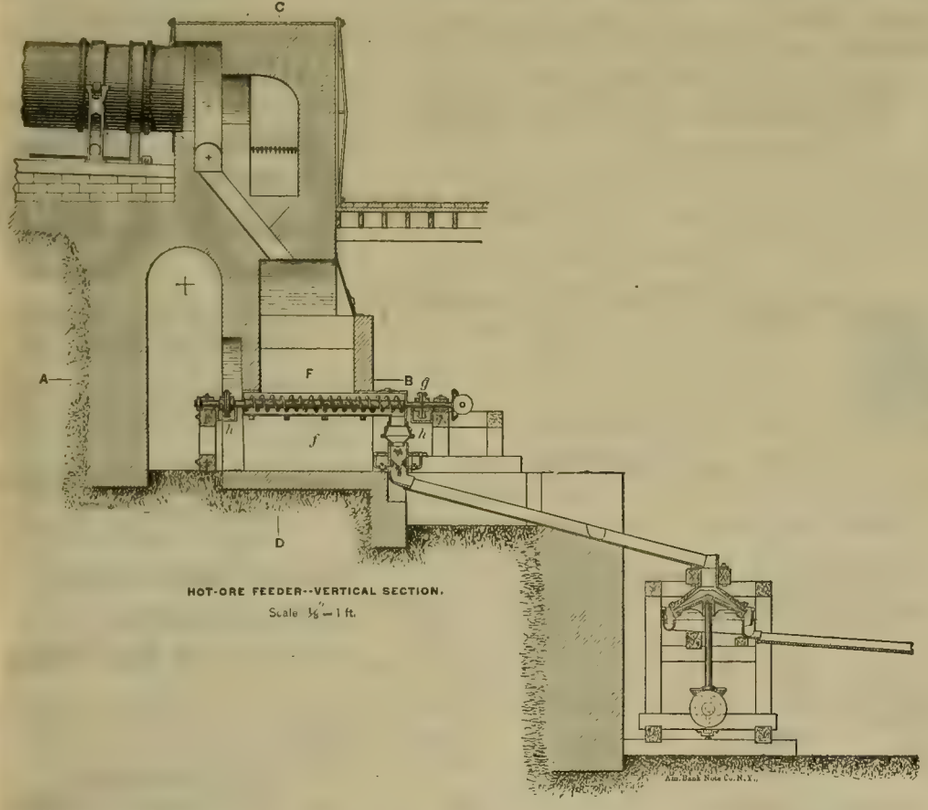
The conveyor discharges the ore direct into the cooling apparatus, as shown in the diagram, whence the water carries it down to the grinding machine. By having for each furnace two bins, which are alternately filled and discharged, oppo tunity is given to increase the chlorination of the silver of an incompletely chloridized ore.

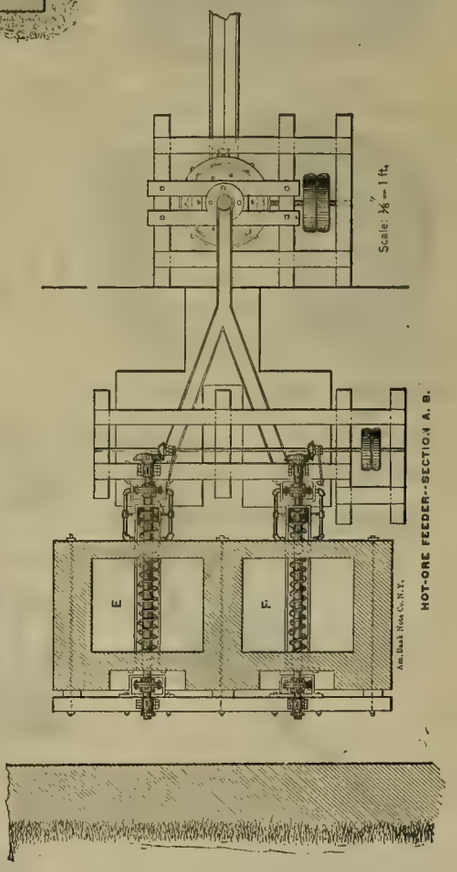
Not all, but most kinds of chloridized ores, when allowed to remain in a mass for some time harden in cooling, especially on the surface and sides; and it will be found necessary in such cases to assist the discharge by poking from time to time from above. To facilitate this, the bin proper is only four feet deep and accessible from the top, as shown in the figure. In case an ore hardens too much, and thus would make the described arrangement impracticable, the bins can be made much larger, but have to be provided each with a discharge door close to the bottom.

A short conveyor has to be placed in front of the bin and right under the discharge door. The end of the conveyor-trough nearest to the door opens in the shape of a hopper, into which the ore from the bin can be drawn by means of hoes in proportions of half a ton or a ton at a time. An ore which has once hardened in cooling and has then been removed, is not likely to harden again, and the conveyor will charge the ore evenly from this small hopper into the cooling tube.

If an ore is to be treated which roasts easily, and no increase of silver chlorination is produced by letting the ore lie in mass, there will be only one conveyor required for each Howell furnace. The ore then will drop directly from the furnace into the conveyor-trough, and will be carried to the base-metal leaching in the same proportion as the battery supplies the furnace with raw ore. In such a case, all operations, from the time the ore passes the rock-breaker until it leaves the leaching works in tailings, will be automatic. When other furnaces than Howell's are used, the roasted ore has to be dumped into bins. Mr. Hofmann does not intend to represent this hot-ore feeding machine for refractory ores as perfect, but with some manual assistance they will perform the work and will give more satisfaction than the present cooling-floor manipulations.







HOFFMANN'S HOT-ORE FEEDING MACHINE.

CŒUR D'ALENE MINES.—We are informed by a gentleman who is well posted on the mining interests of Cœur d'Alene, Idaho, that it is expected the district will, this year, double its last year's product, as all the mines are improving with every day's work.

THE EDISON CONCENTRATOR.—A special to the Philadelphia *Ledger* contains an account of the operations of the Edison concentrator, which concentrates ore, ridding it by mechanical means of dirt and earthy matter.

Removing Concentrates and Sediments from Sluices.

Frederick Sletcher of this city has just patented through the MINING AND SCIENTIFIC PRESS Patent Agency a device for drawing off from a flume, sluice, ditch or similar conveyer the heavier portions of the flowing contents or all the solid matter held in suspension or carried by the water when the sand portions are worthless sediment, as in the case of ditches where it is desired to purify the water as much as possible. It is also applied for saving sulphurets and heavier concentrations from a sluice-box of any width or size through which the pulp of a battery or other valuable mineral-bearing sand or material is carried.

One section of the sluice-box or flume is made separate and has an opening or slot extending entirely across it. By means of rubber or elastic springs this section is connected with the upper and lower corresponding section of the flume or sluice, the slotted section being thus allowed a certain amount of end motion by the yielding of the cushion or elastic springs, without allowing any leakage at the joints.

Beneath the transverse slot or opening in the section is mounted a drum extending the full width and journaled so as to rotate. The slot has its lower side beveled or curved to the same arc with the periphery of the roller or drum so that the latter fits up closely, the upper side being nearly or quite level with the bottom of the sluice. The drum is rotated (by belt pulley) at any desired speed, the direction of motion being against the current flowing down the sluice.

At the end of the drum shaft Mr. Sletcher has arranged a mechanism so that as the drum rotates a series of hammers strike against lugs and produce a jarring action upon the movable flume section, this action being permitted by reason of the elastic or movable joints by which the section is united to those adjacent. The effect of the jars or blows is to produce a temporary stoppage of the water which will have the effect of precipitating the heavier matter downward. The heavier portions of the material flowing through the sluice are precipitated to the bottom, and flowing along until they reach the drum, will fall upon its surface and be carried downward and out of the sluice by its rotation. The drum may be fluted on its periphery. A stream of water is brought against the under side of the drum to remove the material it has carried out of the sluice. In the case of quicksilver, sulphurets, fine gold, etc., as many of these movable sections and discharge drums may be placed at intervals along the sluice as will be found desirable.

MEXICAN MINES.—The Cacachillas G. & S. M. Co., composed of Americans and Mexicans whose headquarters are in San Antonio, Texas, has secured a concession from the Mexican Government for ten years of a right to mine in the whole of the Cacachillas range of mountains which lie about 30 miles southeast of La Paz Lower California. It is proposed to treat the ores by the lixiviation process after awhile, but at present they will be shipped to this city for reduction. Chas. E. Hall, who is connected with the company, says that the machinery will be made in San Francisco, the workmanship and price both being more satisfactory here than in Chicago.

A WATER-POCKET.—A Prescott (A. T.) dispatch says: Advices from the copper mines at Jerome state that in the Wade Hampton mine, on Sunday night, three blasts were put in at the far end of the 800-foot tunnel. Two shots went off, and when the third shot was heard a volume of water shot forth, seven feet high and five feet wide, which lasted for five hours.

WILLIAM KEEHER was badly injured in the North Star mine, Grass Valley, last Saturday, by a rock falling on him.

Comstock Mining Stock Deals.

With the successful introduction of electricity for motive-power, the Comstock mines in Nevada should be mined for generations to come, but whether outside holders of shares in the mines will reap much benefit outside of what can be derived from the fluctuations in their market value is questionable. Many, if not all, the mills built by the mining companies have, by some kind of hocus-pocus, been secured by persons or incorporations whose charges for milling ore are said to be largely in excess of the actual cost, a fair marginal profit above the wear and t ar of the machinery, and also interest on the cost of the mills.

Be this as it may, yet to the dealers in the stocks of the mines' list on the two exchanges in this city, it is not the dividends that have such allurements as rapid fluctuations in the prices of the shares. That these never fail is well substantiated by the history of the deals in mining stocks, although, at times, many months, if not several years, pass before from $10 to $50 on the shares are return. By referring to the old files of the MINING AND SCIENTIFIC PRESS, it will be seen that running from 1868 to 1870 were dark days on the Comstock, when those owning the bulk of the shares of the mines gave out reports that they were negotiating to transfer their interests to English capitalists.

The greatest depression in the market value of the stocks occurred toward the close of 1870, when, commencing with Utah in the north and ending with Benton in the south, 28 of the leading mines' shares sold, taking stock-board quotations, at $4,696,700. Five years later, or at the hight of the Consolidated Virginia and California excitement, they were selling at the rate of over $275,000,000. This was in 1875. In 1877 the market value of the shares had depreciated to less than $30,000,000. These low prices were followed by a higher range in 1878, when the mines were selling at the rate of over $114,500,000 during what was called the Sierra Nevada; shares in the latter mine were sent up from less than $3 a share to nearly $300, a clear profit of about $100 on each and every dollar invested at the low prices.

On April 26, 1884, the same mines sold at the rate of $1,853 000. From this date they advanced under successive small spurts until at one time they sold at the rate of over $11,000,000. From these figures they were sold down, with slight reactions, until in September, 1886, they sold at the low rate of $1,300,000, but by December, in the same year, they sold at over $50,000,000; this deal being chiefly in the North End mines' stock, for Ophir advanced from 60 cents a share to over $30 a share. Within three months from the time these figures were reached, on a big scare, they soon sank down to figures which aggregated a little over $12,000,000. Running through the spring months of 1887, they had attractive fluctuations, reaching at one time nearly $30,000,000, but by May, 1887, they had fallen to about $10,000,000. Attractive but slight fluctuations were had up to the spring of 1888, when what was known as the Confidence deal set in and the mines sold at the rate of about $35,000,000, only to be followed by lower—with at times reactions—prices up to July and August, when bottom figures were touched, for in the fall months values had advanced by turns until they averaged over $4 profit for each dollar invested at the lowest range. Since then the market has been drifting by degrees to low figures until prices this week nearly touched the low figures ruling in August, 1888. What the immediate future has in store for the market, no one outside of the managers of or directors in the pool knows, nor is any one likely to know, for it is by secrecy that successful deals are run.

AN UNDULATING PUDDLING FURNACE.—A Pittsburg ironworker named Anthony Barker is the inventor of what he terms an undulating puddling furnace. As its name implies, the furnace is so constructed that an undulating motion is given to the iron during the process of boiling. When a heat is to be "balled," the bottom of the new furnace adjusts itself automatically, and the process from that out differs but little from the present method of puddling. The inventor claims that the first cost will only be a little over that of the old style, while it will turn out at least double the weight of iron with one more man. A company has been formed to manufacture and introduce the furnace, one of which is nearly in readiness for a free trial at the works of H. Lloyd & Son, Pittsburg, Pa.

Timber for Mining Purposes.

It will be remembered that some months since the Government instituted suits against certain mining companies in Nevada for cutting timber for mining and domestic purposes on public lands. By a resolution of the Senate adopted in January last, the Committee on Mines and Mining was instructed to ascertain all the facts connected with the commencement of these suits, and to inquire if interruption to mining operations had resulted. The committee has submitted its report. The report says that since 1848 the miners have made their own rules and regulations limiting the extent of mining claims, governing the right of possession and regulating the use of lumber and water for mining purposes. The legality of these rules and regulations has been affirmed by the decision of the courts.

The practice of cutting timber was continued, the report says, until 1877, when Secretary Schurz caused prosecutions to be instituted against miners in some of the Territories for cutting timber. The matter was brought to the attention of Congress, and on June 3, 1878, an Act was passed authorizing miners in the mining districts of the United States to fell and remove timber for mining and domestic purposes. The miners treated this Act as a settlement of the question and were not interfered with again for some time. In April, 1887, the District Attorney of Nevada advised the prosecution of miners in that State for using scrubby timber for mining and domestic purposes. Later the Department of the Interior sent a special agent to the State, who was authorized to make a thorough investigation of the alleged cutting. The special agent advised the institution of three suits for timber trespass. The Department subsequently authorized these to be instituted. These suits and seven others were brought in December last, and as a result the two principal mines in Eureka closed down. The conclusion of the committee is that the suits brought by the United States have been a great obstruction to the mining industry in Eastern Nevada; that they are needless and vexatious, and that the Attorney General in authorizing three of the suits must have done so under a misapprehension of the facts.

THE ATLANTA RUBBER CO., Atlanta, Ga., will hereafter look after the interests of the New York Belting & Packing Company, New York, in the Southeast. They will carry a very large stock and complete assortment of their vulcanized rubber goods. The New York Belting & Packing Company is to be congratulated in securing the services of this firm, as the New South is fast developing its manufactures and will constantly demand more and better supplies of this kind, and no one is in a better position to advance their interests in this territory than the Atlanta Rubber Company.

THE Como (Nev.) mining camp is about to awake from her winter's sleep. The Eureka Como, which closed down on December 1st last, will resume operations soon, and it is reported that the Buckeye and also the Rapidan will do some important work this summer. A four-horse wagon-load of "grub" has just gone up for a mining company without a name, who have a valuable property which they intend to begin developing at once.

IT is stated that M. M. Bovard, President of the University of Southern California, has ordered the 40-inch lens, for the great refracting telescope, of Alvan G. Clark of Cambridge, Mass. The telescope is to be constructed on Mount Wilson, and it will probably be two years before it is completed.

THE *Shasta Courier* is becoming discouraged about Lower Springs district in that county, because it has not fulfilled its promise as to paying quartz mines. Several mills have been taken there, run for a time and removed.

IT is understood that the Boston & Montana Co. has a contract secured by certified checks in Boston banks, by which the French copper syndicate secures its output of copper for two years ahead, at 15 cents per pound.

ALTHOUGH San Francisco, among the large cities of the United States, ranks eighth in the number of manufacturing establishments, it ranks first in number of establishments in proportion to population.

WALTER E. BRYANT, curator of ornithology of the California Academy of Sciences, is now making collections in Lower California. This is his second trip in the interests of science to that region.

THE Merriman Manufacturing Co. of Oakland has made an assignment.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

From the official report of U. S. Patents in DEWEY & Co.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING MARCH 19, 1889.

399,827.—GRAIN-CLEANER—Henry Bryan, Modesto, Cal.

399,973. ROTARY FAN FOR FRUIT-DRIERS—J. W. Cassidy, Petaluma, Cal.

399,841.—HORSE COLLAR—Wm. Cosbie, S. F.

399,887.—WINDMILL—G. W. Haines, Adin, Cal.

399,922.—LUNCH-HEATER—T. O'Mahony, Felton, Cal.

399,929.—CABLE RAILWAY CROSSING—G. Provost, S. F.

399,799.—FRUIT GRADER—Volney Rattan, S. F.

399,931. GANG EDGER—H. C. Robb, S. F.

399,791.—CONCENTRATOR — Frederick Sletcher, S. F.

399,708.—HORSE-CHECKING DEVICE — W. P. Smith, Renton, W. T.

399,711. — PLANING MACHINE — M. Stixrud, Seattle, W. T.

399,804.—NAIL—A. S. Wall, Oakland, Cal.

399,829—GRINDING MORTAR—G. W. White, S. F.

400,030.—REEL AND SPRINKLER — R. Wylie, Napa, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GRAIN-CLEANER.—Henry Bryan, Modesto. No. 399,827. Dated March 19, 1889. This is one of those grain-cleaners in which oppositely-vibrating screen-carrying shoes are employed. The inventor has devised a novel mechanism for imparting to said shoes the necessary vibrating or quivering motion. The object is to provide a mechanism which will give the shoes the proper rapidity of motion without having to speed up the driving machinery, and at the same time reduce the friction and wear on all parts. The rockers are curved so that the whole device works easily and with the exercise of but small power.

NAIL.—Adam S. Wall, Oakland. No. 399,804. Dated March 19, 1889. This is an improved nail which the inventor calls a "channel point" nail. The entering end of the nail or spike is divided into two points, so that a V-shaped notch is formed in the end of the spike, and from the apex or bottom of this notch the sides are grooved or channeled upon each side, extending farther up the sides of the nail. The object of this form is to allow the nail or spike to pass in easily as it is driven and without splitting the wood, and also without forcing the wood ahead of it in compressed lumps, as takes place when a square-ended nail is driven.

FRUIT-GRADER.—Volney Rattan, S. F. No. 399,779. Dated March 19, 1889. This machine is used for grading fruits of all kinds according to size. It is a hollow rotating cylinder or barrel having its periphery composed of longitudinal separated slats or bars of tapering form throughout, whereby the spaces between the slats or bars gradually increase in width from one end to the other. Combined with this are independent guide flanges secured separately to the inner surface of each slat or bar, and arranged in a spiral course throughout the length of the cylinder. There is also an exterior rotating clearing drum or roll extending along the cylinder or barrel, and in contact with its periphery for pushing back the fruit which sticks between the slats.

HORSE COLLAR.—Wm. Cosbie, S. F. No. 399,841. Dated March 19, 1889. The invention relates to the class of horse collars, and especially to those known as "short straw" or "wool" collars, the peculiarity of which lies in the fact that the leather of the entire collar is sewed up completely, and is afterward stuffed instead of having the pieces sewed up over the stuffing, as is the case with long-straw collars. This invention refers to an improvement in the top of the collar which consists in a cap piece formed on one end of the back and adapted to cover the joint on the top of the collar, and, in connection with this cap-piece, of an independent piece or strip which covers the straw just under the cap piece and serves as a continuation of the back up to the joint. The object of the invention is to provide in a short straw or wool collar a suitable cap-piece for covering and protecting the joint at the top of the collar, and forming a suitable guide or bearing for the hame-strap.

U. S. SENATE COMMITTEES.—The U. S. Senate Committee on Mines and Mining is composed of Senators Stewart, Jones (of Nevada), Mitchell, Teller, Bate, Faulkner and Hearst. On Manufactures, the committee consists of McMillan, Quay, Platt, Colquette and Blodgett. On Patents, Teller, Chace, Platt, Hiscock, Gray, Kenna and Reagan.

TIOGA DISTRICT, in Tuolumne county, just over the boundary line of Mono, has some very good claims which are soon likely to attract more attention. Senator Hearst has recently bonded a property in the district, and will, this spring, prosecute developments upon it. The ledges are large, and some of them assay high in both silver and gold, the former predominating. The percentage of sulphurets is large. There is an abundance of wood and good water-power is available. It is probable that the ores will be concentrated and shipped. Men have been working in the district for some years, but it is only now that the attention of capitalists has been called to the mines.

HANDY MIXTURE FOR A MACHINE SHOP.—It has been stated that soft soap, with half its weight in pearlash, one ounce of mixture in about one gallon of boiling water, is found of great practical value in engineers' shops, in the drip pans used for turning long articles bright in wrought iron and steel. The effect of this mode of treatment is that the work, though constantly moist, does not rust, and bright nuts are immersed in it for days till wanted, retaining their polish.

LAST week's official report from the Consolidated California and Virginia shows an improvement in both the quantity and grade of ore shipped, and it is now certain that the yield of the mine the current month will cover operating expenses and the April dividend. The average grade of ore now being extracted from the mine is as high as at any time since the development made in 1886.

JAMES R. COLLINS, the well-known millwright, died on Sunday in Oakland. For some years he has been engaged in the construction of a number of mining works of a superior character, such as the Providence mill, at Nevada City, and others at different places in the State. His last work was on the new mill of the Pittsburg Mining Co., being the contractor for doing the wood work.

THE TANNER HILL MINE.—A dispatch from Sutter Creek, Amador county, says: Tanner Hill mine, lying between the Oneida and the old Eureka or Consolidated Amador, on the mother lode, has been secured by Dr. J. L. Mayor and Jackson Dennis of this place. The people of this place look upon it as the initial step to opening one of the largest bonanzas ever developed on the lode.

AGAINST A MINING COMPANY.—Judge Lawler has rendered judgment in the case of A. Judson against the Empire Mining Company in favor of the plaintiff for $12 569 77. The suit was brought to obtain money advanced to the defendant company between Sept. 20, 1886, and Aug. 16, 1887, together with interest and $900 claimed to be due for services rendered.

WELLS, FARGO & Co. have moved into their fine new building, corner of New Montgomery and Mission streets, in this city. This building has been constructed especially for the carrying on of the express business, at an expense of $225,000. It is four stories high and is built of pressed brick and terra cotta. The offices in the interior are finely fitted up.

SUTRO TUNNEL CO.—The adjourned meeting of stockholders of the Sutro Tunnel Co. was to have been on the 28th, but was again postponed for the lack of a quorum. The impression prevails among the better-informed that a quorum is not likely to be had until in July next, or soon after the time expires for the redemption of the property.

BOILER EXPLOSIONS.—The total number of boiler explosions reported in England for the year ending June 30, 1888, is 61, the number of persons killed being 31. In the United States, where the number of boilers is presumably about the same as in Great Britain, the boiler explosions in 1887 amounted to 198, the loss of life being 264.

THE Santa Fe *New Mexican* says: It is stated that the bottom has completely fallen out of the wagon-roads between Cerrillos, San Pedro, Dolores and other points in the mining districts. This state of affairs has served to delay many mining enterprises. At best the roads cannot become good before April 1st.

SILVER REEF, the sandstone silver camp of Utah, has run down badly, and miners are beginning to leave. The Christy Co. has closed down mines and mill, removed machinery from the California mines, and is doing nothing except to keep pumping at the "New" shaft.

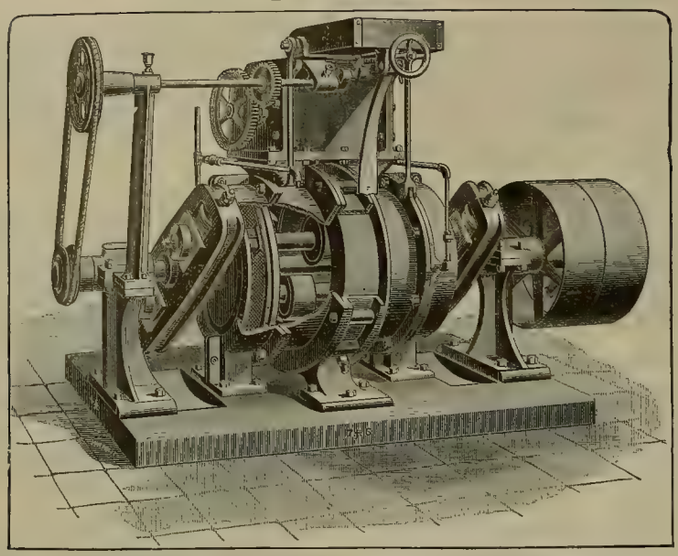
THE large clock which will grace the tower on the new *Chronicle* building, corner of Market and Kearny streets, will have the largest dials in the United States. The diameter of each dial will be 16 feet. The tower will be 203 feet above the sidewalk.

THE number of gallons of water required for a boiler per horse-power per hour may be safely estimated by adding 15 to the pressure per square inch in pounds; divide the sum by 18, and multiply the quotient by 24.

THE Mount Morgan mine, Queensland, is now paying dividends at the rate of $500,000 per month, with a probability of a continuance for a long period.

FRISBEE WET MILL.

This Mill, with a weight of less than 9000 pounds has a capacity of three tons per hour of hard quartz to 40 mesh; has been thoroughly tested; we guarantee its work as represented, and we will give long time trial.



IT HAS NO MORE WEARING PARTS THAN CORNISH ROLLS,

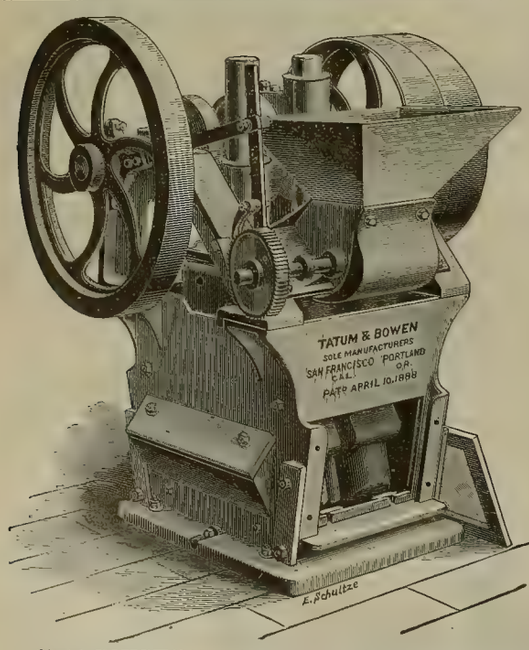
And renewals will not cost over one-half as much as for stamps. Will run empty, or with small amount of ore without injury. The attention of parties having Cement Gravel is called to this Mill, as it will run 100 tons per day to No. 8 mesh; 30 to 35 H. P.

OUR DRY MILLS are the most economical ever built, and are extensively used with record of several years. No grinding in pans. Mill finishes to any fineness desired.

FRISBEE-LUCOP MILL COMPANY,

GIDEON FRISBEE, Manager, - - - 32 First Street, San Francisco.

HOOKER & LAWRENCE, Gen'l Ag'ts. 145 Broadway, New York.



—THE—

PERFECTED DOUBLE Economic Quartz Mill.

Attached to each Mill is an effective

Automatic Ore Feeder.

THE CRUSHING is done by the rapid rocking movement in OPPOSITE DIRECTIONS of two heavy castings, the bottoms of which are slightly circular in form, and each provided with four shoes.

The Mill is a closer Gold-Saver and catches a larger percentage of the Clean-up in the Battery than any other Mill.

It costs less, in proportion to what it will do, than any other mill. There are no working parts to buy for it, no matter how long it is used, except shoes and dies. Capacity of Mill, 6 to 10 tons per day. Weight of Mill, complete, 6400 pounds.

We manufacture, to go with the Mill, an

IMPROVED ROCK BREAKER.

Power required for Mill and Rock Breaker, 6 H. P. SEND FOR CIRCULAR. Address:

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, March 28, 1889.

General trade shows a steady increase. While the distribution trade is said not to be, as a rule, up to that which obtained at this time in 1888, the tone appears to be healthier and the condition or situation based on a more permanent foundation. Interior merchants are not carrying large stocks of goods, seemingly preferring to buy in an assortment way until the season is further advanced so as to admit of a clearer idea of the outlook for the future. Among iron workers there is still a feeling of uncertainty, which, no doubt, is further strengthened by the action of the lumber trust in advancing the price of lumber, with still higher prices intimated. The advance in lumber, it is feared, will operate against any decided building boom.

The local money market is reported to be easy, with remittances from the interior larger than at this time in 1888. Receipts of treasure the past week by sea are as follows: Coin from Guaymas, $1300; Mexican ports, $10,735; Honolulu, $8960; British Columbia, $3821. Total, $24,816. Gold dust from Tumaco, S. A., $1020; silver bullion, $126,686 from Mexican ports. There is a continued good inquiry for exchanges on the East, which causes the rate of premium to be firmly maintained at 10 to 12½ per cent for sight, and 17½ to 20 per cent for telegraphic. The call is chiefly from importers, who have maturing bills to meet or else wish to discount their bills. The speculative markets have been rather quiet the past week, so that the call for funds for dealing in wheat options, mining and local securities has been light. But the general impression is that the present quiet presages more activity in the near future.

SILVER—The market held steady at 92⅞ to 93c up to Tuesday, when an advance of ⅛c was established, only to be followed by a reduction of ⅛c. The sales the past week were larger, owing to freer receipts from Mexican ports, and exchanges continuing strong.

MEXICAN DOLLARS—The market has shown a fair degree of activity for shipment to China, but not to the extent that obtained the preceding week. The price paid ranged from 73 to 73¼c from first hands.

QUICKSILVER—Receipts the past week were as follows: J. B. Randol, 100 flasks; C. S. Neal, 35; Parrott & Co., 33; and Haas Bros., 65. Total, 233 flasks. The market is steady, with an improving demand. There was shipped to Guaymas the past week, 100 flasks.

BORAX—Receipts the past week aggregated 752 cental, and shipments, 11 tons to Detroit, via Canadian Pacific railway. The market is steady.

LIME—Receipts the past week aggregated 2778 bbls., and shipments, 575 bbls. to Honolulu. The market is reported to be easy.

TIN—Both pig and plate are very strong for immediate delivery, owing to a good demand from up North. A large consignment of plate is due, and until that arrives, the market will hold strong. The consumption is very heavy this year.

PIG LEAD—A continued good demand is reported from the North. Local canners are not buying much yet, owing to the high price of tinplate.

PIG IRON—The market is very quiet, with both exporters and consumers apparently awaiting developments. The European markets are stiff, which counteracts the effects of a shading in freights. The low prices ruling at the East may induce shipments via Cape Horn.

COAL—Imports the past week were as follows: 2625 tons from Nanaimo; 4079 tons from Australia; 1800 tons from Tacoma; 800 tons from Coos bay; and 194 tons overland; total, 9498 tons. The market is reported to be barely steady. Large consumers are well stocked, while the others are rather disposed to follow the market than to stock up even at present low prices.

COPPER—The last steamer to New York took out 1356 lbs. The market is unsettled, and will continue in this condition until a more definite understanding is arrived at in Europe. So far, all information tends to confirm previous received advices, that a very strong combination or syndicate will be formed, so that prices will not go much, if any, over 13c at Eastern tide-water.

Eastern Metal Markets.

By Telegraph.

NEW YORK, March 28, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42⅛	93¼	$16 50	$3 67½	$21 10
Friday	42⅛	93¼	16 10	3 67½	21 05
Saturday	42 9-16	93¼	16 00	3 67½	21 20
Monday	42½	92½	14 75	3 65	21 10
Tuesday	42½	92½	14 75	3 67½	21 05
Wednesday	42 9-16	93	14 25	3 65	21 05

NEW YORK, March 28.—Quicksilver continues unsettled and weak, with slight fluctuations reported. Lead is still heavy in sympathy, to some extent, with copper. Large consumers still hold off. Tin has ruled weak, with buyers offish. Borax is without essential change. In pig iron the market appears to have a slightly steadier tone, although the sharp competition, heretofore reported, by Southern iron men is continued. The latest sales made of Southern was at $14. This low price demoralizes Pennsylvania iron men, who find that as fast as they ease off, Southern is offered at a fraction less to induce consumption.

THE SANHEDRIN MILL & LUMBER COMPANY have recently contracted with the Vulcan Iron Works for the machinery for their new sawmill to cut about 50,000 feet of lumber per day, and have also selected a 60 inch heavy "Vulcan" gang edger, a set of heavy "Vulcan" fractional screw head blocks; also, an "8x10" "Campbell" steam feed.

A JUDICIAL inquiry into the formation of the copper syndicate has been commenced at Paris.

Mining Share Market.

The volume of business the past week in mining stocks was larger, but at lower figures up to Tuesday, when a natural reaction set in. The lower range of values brought about by cross-orders and street pointers uncovered quite a line of marginal stocks, besides frightening many of the more timid holders into selling. It is generally claimed that the pool engineered the decline so as to get more cheap stock. While there are reports of assessments to be levied, there is very little news of a reliable character from the mines. This condition of affairs, even with a report that several mining-stock magnates will soon be here, causes an uneasy, bearish feeling to obtain with outside operators. The general tenor of private information from the Comstock mines is to the effect that prospecting and developing work of a very important kind is going on in several of the mines, but how long before "the powers that be" are prepared to make a favorable showing is, as yet, an unsolved problem. The work going on is still toward the West or Red lode, and as distance is gained in that direction, the more certain becomes the belief in its richness. Although there is an abundance of water, yet no more stamps are dropping.

Confirmation of the improvement in the mines mentioned in our last week's report has been received at headquarters. This week private advices report still further improvements, but particulars are not given.

An assessment was levied the past week on Peerless and also on Bodie.

The ore yield of the Comstock mines during the week ended March 23d aggregated 5553 tons, divided as follows: Consolidated California and Virginia, 2717 tons, battery sample assays showing a value of $35.10 per ton; Savage, 505 tons, assaying $21.37; Hale and Norcross, 625 tons, assaying $28.06; Confidence, 658 tons, assaying $27.07; Crown Point, 808 tons, Overman, 301 tons, Justice and Alta, 500 tons, Gould and Curry, 65 tons, assaying $19.28. The bullion yield of the above was about $140,000.

THE Reese River *Reveille* thinks that while it may be all right to build a dam across the Carson river to store up water for the quartz-mills, it does not like the idea of taking the money for the purpose from the School Fund.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, term of subscription, and give it their own patronage, and as far as practicable aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or of some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

CALIFORNIA CASKET CO., March 25. Object, to manufacture and sell all kinds of undertakers' goods. Capital stock, $300,000. Directors—Wm. P. and C. H. Morgan, George P. Thurston, James F. Pierce and John F. Finley.

CARBON PAINT CO., March 26. Object, to manufacture and sell carbon paint. Directors—A. L. Minson, James Stratton, A. T. Heyden, R. W. Andrews and E. L. Collins.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Navajo, March 26, $8000; Cons. Cal. and Virginia, 26, $72,240; Moulton, 16, $26,880; Alice, 16, $24,336; Lexington, 16, $21,596; Blue Bird, 16, $37,040; Hanauer, 19, $5300; Hanauer, 20, $2000; 23 $11,000; Navajo, 23, $8000; Savage, 23, $3700.

Testing and Working Silver Ores

An illustrated work of 114 pages, for miners and prospectors, by Chas. H. Aaron. Mr. Aaron has managed to give many useful hints and suggestions, free from all technicalities, and in such a style as to be easily comprehended. It is written for the miner, with no chemical symbols or metallurgical technicalities to confuse those who are not chemists or metallurgists. The following summary of the contents of the work will give an idea of its scope.

Under the heading of the first chapter, "Testing Ores for Silver," we find paragraphs on ore formation, test for silver, with heat and water, acid or blow pipe. In speaking of testing for a process, the extent and richness of ore is considered, smelting ores, selecting and working samples, appliances for testing, roasting, etc. Under the head of "Working Ores" the author describes Aaron's process, has something to say of superheated steam, preparation of dichloride of copper and protochloride of copper, use of copper and iron, quantity of chemicals, carbonate of lime, chloride ores, amalgam, Patchen's process, etc. He also describes the methods of working roasted ores, treatment of base metals, stirring, heat of furnace, want of sulphur, etc. Under the head of "Leaching Processes" are the titles Smelting, Mexican process, Chilean process, Kroehnke's process, etc. Under "Pulverizing Machines" are described the arastra and its construction and operation, stamp batteries, screens, Crocker's trip-hammer battery, Paul's pulverizing barrel, Kendall's battery, Noice's pulverizer, a cheap rock breaker, etc.

In speaking of amalgamators the author describes a cheap amalgamator, grinding the ore, directions for making a barrel, preventing mechanical wear, use of quicksilver, copper in bars, Freiberg barrel, cheap barrel trough, barrel on rollers, Aaron's amalgamator, separator, etc.

He describes an improvised retort, roasting furnace, furnace tools and furnace building. Among the miscellaneous mention may be found Aaron's leaching apparatus, with two or three different arrangements, a small mill, sampling tailings, and settling tanks, dichloride of copper, etc. Mr. Aaron is a practical miner, of long working experience on this coast.

Price, post free, $2.00. Sold by DEWEY & Co., Publishers, 220 Market St.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulæ, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated:

General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulæ Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulæ and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water Over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow Through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water Through Short Tubes and Compound Tubes; Flow of Water Through Pipes; Tables of Velocities and Cubic Feet Flows for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow Through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, $2.00, post-paid. Sold by DEWEY & Co., Publishers, 220 Market St., San Francisco.

Books on Working Ores.

By GUIDO KUSTEL, M. E.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. By GUIDO KUSTEL, M. E. 1880.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty PRICE, $3, coin, postage free. Sold by DEWEY & Co., Publishers, 252 Market St., San Francisco, Cal.

By C. H. AARON.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, $3. Sold by DEWEY & Co., S. F.

For New Subscribers—Something New and Rare.

PACIFIC COAST RELIEF CHART.

PHOTO-FACSIMILE.

With subscription paid one year in advance for this paper, and 10 cents to pay postage and mailing tube, we will send a fine Photoplate Relief Chart of the Pacific Coast, embracing California, Nevada, Oregon, Washington Territory, and part of Montana, Idaho and Utah, Photographed from a topographical relief model in plaster 15 feet 3 inches by 5 feet 6 inches in size), made recently by Isaac Winston and Prof. Geo. Davidson (the latter Chief of the U. S. Coast Survey on this Coast for the past 20 years).

While it does not take the place of an ordinary map, it illustrates, comparatively, the elevations and depressions of the principal mountains, valleys, rivers, lakes, ocean and bay shores of the Pacific States and Territories, and makes a permanently useful, handsome and desirable picture for either library, office or home.

The charts are 19x24 inches, well suited for framing, if desired. It is as handsome, and even more durable, than an ordinary photograph. Seldom is so choice an article offered as a newspaper premium. Sent to old subscribers on the same terms on paying one year in advance of current date. Subscribe and secure this permanently valuable chart.

Address Publishers of this paper, No. 220 Market St., S. F

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Every Miner His Own Assayer.

A chemical for testing and ascertaining the value of all kinds of ore, by which every miner and prospector can make his own assays, anywhere in the mountains, at a cost of a little over 5 cents and in a few minutes' time. No apparatus or dangerous acid needed; a dry powder, which may be carried in the pocket. This, mixed with the ore and a little water in a teacup, produces an electric current, which separates the silver from the ore instantly, no matter how refractory. Try it; you will be delighted. Will save you many dollars for assaying. Package sufficient for 30 tests, with full directions, by mail to any address on receipt of $2; 6 packages for $10. Address, Prof. J. Herman, P. O. Box 1845, San Francisco, Cal.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

ASSESSMENT NOTICE.

Gray Eagle Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Placer County, California.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 19th day of March 1889, an assessment, No. 12, of Five Cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Room 9, No. 327 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1889, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 14th day of May, 1889, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.

OFFICE—No. 327 Pine Street, Room 9 S. F. Stock Exchange Building, San Francisco, Cal.

The Celebrated H. H. H Liniment.

The H. H. H. Liniment is for the treatment of the Aches and Pains of Humanity, as well as for the ailments of the beasts of the fields. AGENTS FOR THE PACIFIC COAST OF

BRYAN'S ROLLER QUARTZ MILL,

The most perfect Roller Mill made, for the following reasons:

1. It is cheaper.
2. It is more durable.
3. It crushes a larger amount of ore with less power.
4. It amalgamates a larger percentage of the gold.
5. Its "clean-up" is quicker and fuller.
6. It is portable, requires no frame-work, and is ready for the foundation as it leaves the shop.

Full Descriptive Circulars of any of the above sent on application.

OFFICE OF THE CANDELARIA CONSOLIDATED MEXICAN MINING CO., SAN DIMAS, DURANGO, MEXICO, October 25, 1888.

Risdon Iron Works, San Francisco—GENTLEMEN: Our Company has been operating three of the 4-foot Bryan Roller Quartz Mills, one of which has been running steadily for three years, one for two and one for one year. Our quartz is very hard; we crush through a No. 60-mesh screen. Our mills run 55 revolutions per minute, and each crush through 60-mesh screen 12 tons in twenty-four hours; through 50-mesh, 15 tons; and through 40-mesh, 18 tons. This proportion has been continuous. One set of Dies will crush from 1500 to 1600 tons. One set of Tyres will crush 1500 tons. One ring plate will crush from 2200 to 2300. The mills require very little attention. At our mill an ordinary "peon" earning one dollar per day has complete charge. In regard to sliming, in comparison with stamps by reason of the discharge surface and the continuous agitation by the scrapers, a MUCH less amount of slimes is created. A three years' experience teaches me that, in every respect, the mills are a complete success and of material benefit to the mining world. They can be set up and running in 48 hours, and can be dismounted in the same time and removed to wherever desired. Ours were packed on our mule trail over as difficult a road as any in Mexico. As a gold amalgamator, it is unequaled by any mill now in existence.

Yours truly, D M. BURNS, Superintendent.

New York Office, 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

VOLUME LVIII. Number 14.

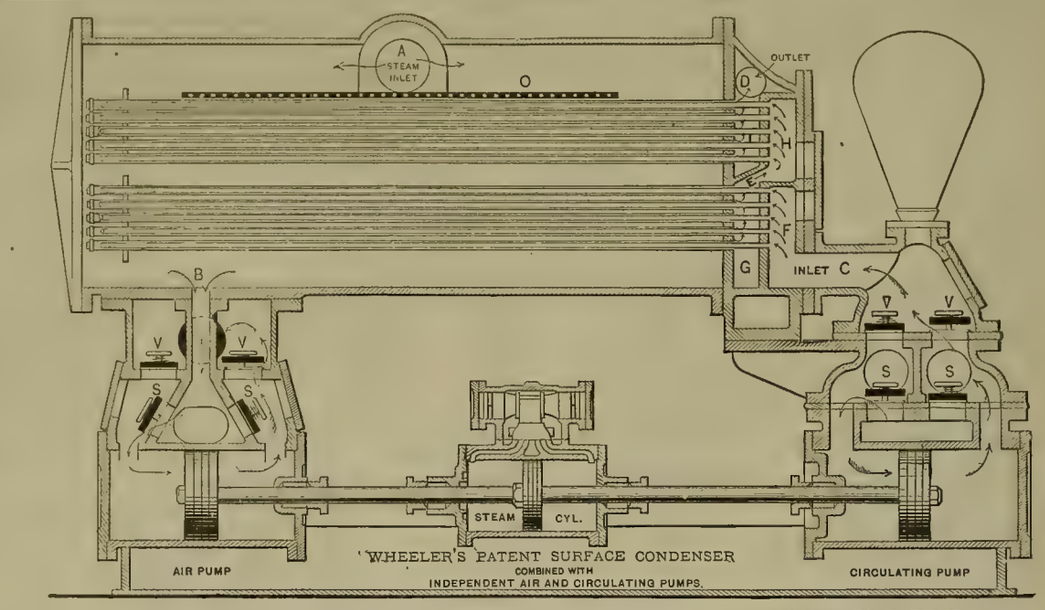
Wheeler's Improved Surface Condenser.

The accompanying cuts illustrate the combination of the Wheeler surface condenser with independent system of air and circulating pumps. The condenser is mounted on the latter, thus saving floor space, which is of considerable importance in engine-rooms that are crowded with machinery, such as are found on many steam vessels and in numerous factories located in crowded towns and cities. In this design the condenser is firmly bolted down on the pumps, the latter serving as a foundation, thereby saving expense of piping between the pumps and the condenser. As shown by the sectional view, the water-pump delivers the circulating water through the nozzle *C*, directly into the lower section of tubes in the condenser. From thence the water flows by the passageway *E* into the chamber *H*, passing through the upper group of tubes, and finally discharging at the outlet nozzle *D*, as shown by the arrows. The exhaust steam entering at the nozzle *A*, comes in contact with the scattering plate *O*, thereby distributing uniformly over the cooling surface of the tubes. The water of condensation gravitates to the bottom of the condenser, and flows directly to the air-pump by the annular passage *B*, the air-pump discharging the water through the outlet nozzle at the side of the cylinder. Both air and circulating pumps are operated by a direct-acting steam cylinder in the usual way.

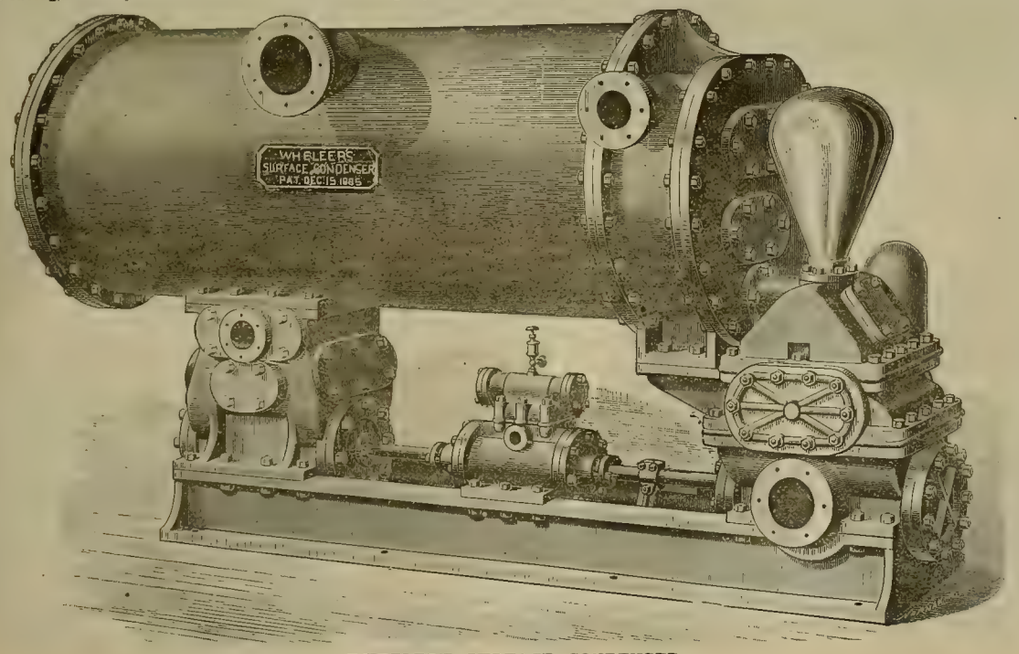
In our issue of Jan. 30, 1886, we gave a sectional view of this improved surface condenser, showing more of the details of construction. It may be well to state here, however, that the arrangement is one providing very thoroughly for the expansion and contraction of the tubes, and this without the use of tube packings of wood, paper, or similar materials. In fact, there are no ferules, washers or packings of any kind employed. The tubes are seamless brass tubing, carefully tinned inside and outside. The tubes are arranged in pairs, the smaller tube inside of the larger. The latter is thickened at one end, on which a deep thread is chased. This end of the tube is screwed into a head of brass, and on the other end of the tube is screwed a cap, as shown. One end of the small tube is also drawn thick and a thread chased on same. This tube is also screwed into a head of brass. The tubes can be easily taken out and thoroughly cleaned, as their form and the manner of fastening permit of this being readily done.

The tightly screwed fastenings for tubes also permits the use of circulating water under pressure, which is often the case with stationary engines where the supply is from a head of considerable hight. In other words, there are no tube packings of any kind to be forced out or loosened by pressure of the circulating water.

The circulation of water is very thorough, and consequently the smallest amount of cooling-water is required. This feature gives a marked saving in the power necessary for circulating pump. The condensers are made with bodies of both circular and rectangular shape. The larger sizes are usually of the latter design.



SURFACE CONDENSER COMBINED WITH INDEPENDENT AIR AND CIRCULATING PUMP.



WHEELER'S SURFACE CONDENSER.

The patentee and proprietor of these improved condensers is Mr. Frederick M. Wheeler, 93 and 95 Liberty street, New York.

Manganese Ore.

There does not appear to be very much money in manganese mining, though some 1500 tons were mined in this State last year. The principal producing States are Virginia, Georgia, Arkansas and North Carolina, which produced in 1887—the latest available statistics—34,524 tons, worth $333,844, or $9.67 per ton.

The average value of the ores of the several States varied in that year from $2 in North Carolina to $12.79 in Virginia, the Arkansas value being $5 a ton, and Georgia value $5.74. The range of values in Virginia was from $4.13 to $20; in Georgia from $2.50 to $6.50, while in Arkansas the uniform price of $5 was given as the value of the ore. These values are free on board carts or cars at the mines. Where ore is sold delivered on cars at localities distant from the mines, the cost of carting the ore to cars or to the locality is to be deducted from the f. o. b. price.

Virginia produces most of the manganese ore mined in this country, its production in 1877 being 19,835 tons out of the total 34,524. This ore comes from the Crimora mine.

It is estimated from the best data obtainable that the production of manganiferous iron ores containing silver in the Rocky mountain regions in 1872 was some 60,000 tons, valued at $10 per ton. These ores are not utilized for their manganese directly, but for their silver, the manganese they contain adding to their value because of its fluxing qualities.

Manganese is mined in quantities in Nova Scotia, Belgium, Cuba and Great Britain.

The ore mined in this State last year brought about $20 a ton in San Francisco.

Boston suffered next to Paris in the copper crash. The stocks held in the Hub shrunk just $28,000,000.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS.

Raining Rocks.

Meteoric Stones and Rural Philosophy.

EDITORS PRESS:—Probably the year was A. D. 1858—or along there somewhere—when I took a ride with a high-toned peddler of dry goods and notions in the counties of Muskingum and Guernsey of the State of Ohio. The season was summer, or at least the weather was warm. This peripatetic merchant was a man prone to display, and his wagon was an artistic evolvement of the wainwright's mysteries; the run gears were delicate and beautiful to look upon, yet strong and tough as the celebrated white-oak, ash and hickory woods of that country could warrant; the bed, or box, was constructed with a system of shelving inclosed in a painted shell of clear poplar lumber, highly polished, and in shape like an oblong square, one-roomed house, one story high, with a roof on it pitching gently right and left, from side to side; and all the woodwork of this wagon was painted a bright red, except the delicate blue penciling on the wood of the wheels and the bright glossy black on the ironwork. Above this wagon-box at the front was a black leather top, like a buggy-top, covering the seat. The outside of this painted shell could be let down at each side and at the tail, resting upon suspender chains from the frame of the shelving, and when let down, either one or all three of these parts could be used as counters on which to display, and from which to sell, goods, wares or merchandise. In front of this mercantile vehicle trotted or pranced four jet black horses.

[NOTE.—This description of an ancient peddling-wagon is for posterity; to show to the later-born and unborn readers of the PRESS (and may they be thousands upon thousands, Selah.) that their ancestors, "away back in the States," were no slouches in the peddling line when the grizzly bear on the California State shield was only a cub.]

Well, as I was about to say, I was journeying with the peddler, riding on the comfortable seat of the wagon aforesaid, and heading for the town of Cambridge, when, suddenly and without warning, a missile (afterward found to be a black stone about an inch and a half irregularly square) struck the highly polished roof of the wagon-box behind us. "Whoa!" exclaimed the merchant, as he stopped his team with an instantaneous twist of the reins around the brake-lever, and off he went down under the wagon, where he employed himself for a moment in crawling under the forward axle-tree, so as to unhook the traces of the wheel horses. I, of course, without exactly knowing why, had promptly followed the merchant, and as we both sat, sort of flat, down underneath the wagon, I asked: "What's the matter? What's up?"

"Nothing up," says he, "but something down. I can stand most any kind of a shower; but when it rains rocks, I want to get on the underside of something hard."

There was a kind of whizzing roar in the air when the thing struck the wagon roof, and also a wide scattered plumping, or, maybe, it was a pattering, all about; but the phenomenon only lasted about half a minute of time.

Hearing no more disturbance in the air, we crawled out and up, after re-hooking on the wheel horses, and went on our way, in no wise, so far as we could see, damaged other than a shattered hole in the roof of the wagon-box—a hole which looked to have been shot there by a large ball from a small cannon or a big shotgun. I asked the merchant why not stop and examine into the matter; but he said he wanted to get out of a place where it rained rocks, and he drove right along until we came to the small settlement where he expected to remain over night and "trade with the natives." Upon examination he found the little black rock where it had fallen into a pile of woolen comforters—a kind of knit neck wearing goods—and although the black stone was, at the finding of it, cool enough, it was evident that it was warm, if not hot, when it lodged there; for it had roasted the woolens right next to its surface as if they had been scorched by a sad-iron, a little too hot for family use.

That evening at the little cross-roads village the merchant had quite an audience to listen to his story, examine the black stone, and buy small articles of various merchandise. And at night, after supper, in the public room of the half-tavern half-farmhouse, we had an immense conversation on the subject of meteors, falling stars, shooting stars, etc., and one elderly person related the story of the shower of falling stars—in 1833 I think he said it took place.

Well, we had a very interesting time at that half-tavern that night. I have never heard so much variety of strictly original scientific astronomical opinion in all my life. They were nearly all willing to believe our story about the shower of stones, because most of them had heard the roaring noise at the time we spoke of. They were old-fashioned Western farmers and laborers, none of whom had what they called "book larnin'," and nearly all of them said they had "heered that nize," and one of them "sort o' thort he seed sumfin most like to er fli spec' atwuen him an' the sun, but wa'ant shore what it *could* be tell he heered about this yer rock a-hittin' the peddlin' wagon."

But as to where that stone could come from, that was the "main pint afore that ordience." Several of the cereal Solons thought "hit must er come from the moon." But "wher wer the moon at that time er day?" To which last question the merchant—the traveling merchant—ventured to remark that it didn't matter where the moon might happen to be that day, at that hour, because if that stone came out of the moon and the moon being millions of miles distant from the earth, then that stone must have started on its journey several years ago. To this last statement the crowd responded:

"Gosh!"

And then we all retired for the night.

Next morning, after a little more trading in dry goods, we strung out the black horses and wended, and, along toward evening, we arrived at the town of Cambridge, and there our story of the falling stones dwindled into smallness, because they had there a black stone of over sixty pounds in weight which had fallen hot, down from the upper air, about the hour that we dodged from the shower of stones.

This meteoric stone—the sixty-pounder—was exhibited for some time as a curiosity, and finally found permanent lodgment in some scientific museum—the name of which museum I could remember years ago, but not now.

The moral of this sketch is that when rocks are raining it is no cowardice to seek shelter.

J. W. GALLY.

Watsonville, Cal., 1889.

California River and Harbor Commission.

P. A. Humbert, one of the Examining Commissioners on Rivers and Harbors, in conversation with a reporter, thus outlines the work of the Commission:

"We intend going to work immediately, and we confidently believe that our labors will be of great benefit to the State. There has been adverse criticism on that section of the Act under which the Commission was appointed which authorizes us to employ such persons at such compensation as we may deem proper as surveyors or assistants in any of the work; and the prediction has been made that we would squander the people's money. That wording is very broad, I admit. As it stands, if the people will trust us, they will find that we will not take advantage of them. The Commissioners appointed by the Governor are State Engineer W. H. Hall, Charles Reed of Yolo county and myself. The character and experience of the gentlemen composing the Commission should be some guarantee that the work will be honestly and economically done. I am confident that the expenditure of $25,000 or $30,000, under our direction, will lead to the appropriation of from $250,000 to $500,000 by Congress next winter for the improvement of our rivers.

"Such appropriations have been made heretofore, but the money was to be expended under the direction of the regular army engineers, and we could not show these officers that it would be expended judiciously. They would say, 'What is the use of the Government spending $200,000 in dredging the Sacramento river this summer when the high water next spring will fill it up with slickens again?' And we could only answer, 'There is none.'

"Now our duty, quoting the Act under which we hold our appointments, is to determine what steps are necessary for the rectification and improvement of such rivers (the Sacramento and others) and streams, and make or cause to be made all such necessary and proper surveys, examinations, maps, designs, drawings, estimates, specifications and exhibits as will enable the Congress of the United States to clearly understand the condition of such rivers and the cost and expense of properly rectifying and improving the same.

"Now you see what we are to do. We are to make a study of the Sacramento river and show Congress and those army engineers how the money of the United States can be spent to advantage in its rectification and improvement. The State has spent from $300,000 to $400,000 for a study of an irrigation scheme. The maps and plans which were made for this purpose are now in the State Engineer's office at Sacramento, and in them we have the basis of our work. They show the soundings, which are necessary to an understanding of the subject, and it is because we have them that our work will be comparatively inexpensive.

"There was no appropriation made for our work by the Legislature, but we are satisfied that the Sacramento river people will advance all the money that we will require, and trust to the next Legislature to reimburse them.

"It is our intention to begin work immediately. We will call a meeting of the river men and lay the matter before them. Then we will take a trip up the river, with Hall's plans, and determine what ought to be done."

ALASKA BOUNDARY AND GOLD FIELDS.—The recent discovery of gold near "Forty-mile Creek," Alaska, has moved the Government to fit out an expedition to ascertain the true boundary line between that country and British Columbia. There will be four parties of ten men each, under the command of J. T. McGrath, J. H. Turner, J. J. Gilvert and J. F. Pratt respectively. The commanders of the different parties are all trained engineers in the employ of the Geodetic Survey, and in addition each party will have a physician and naturalist in attendance. The expedition will start in June, and it is expected to remain away 18 months.

Notes on Leaching Silver Ores.

NUMBER I.

[Written for the MINING AND SCIENTIFIC PRESS by C. H. AARON.]

Ottokar Hoffmann, M. E., has been enjoying an enviable opportunity, a result of which is a series of able, interesting and instructive articles on lixiviation in the *Engineering and Mining Journal* of Feb. 9th, *et seq.*, in the present year. An English company bought the San Francisco Del Oro mine in Parral, Mexico, the ores of which had been worked to a certain depth with profit, but at last became so difficult that no one could be found able to treat them. The company engaged the services of Mr. Hoffmann and wisely gave him not only a mill with a Stetefeldt and a Howell furnace, but also *carte blanche* to put up anything he might require for the purpose of experimenting. Mr. Hoffmann has made good use of his opportunity to judge from his articles, and has generously given the public the benefit of his experience.

This shows one of the benefits of a patent law which, by protecting inventors, makes it an object to somebody to urge the adoption of an improvement. The Russell patents have led to more discussion of and attracted more attention to the subject of silver leaching than anything else that has occurred for some years, and Mr. Hoffmann's articles bear internal evidence that some of his investigations were suggested by that discussion and by the claims of the advocates of that process; at the same time he has his own patented method to present to the world, which detracts not from the merit of his articles.

Mr. Hoffmann states that the Russell process at the "Cusi" mill in Mexico was a failure, and that better results with larger profits have followed the return to the ordinary system. He attributes the failure of the Russell process to imperfect roasting of the ore, and very properly observes that it is always better to roast as well as possible than to rely on any "extra solution" for the rectification of the results of neglect. These articles also show that the Stetefeldt furnace is not adapted to the roasting of the ore of the San Francisco del Oro mine, which contains large proportions of zinc blende and galena in a calcareous gangue, with a small proportion of pyrites. Not only does the Stetefeldt furnace fail in roasting the ore, but also completely spoils it for further treatment in another furnace, by melting it to globules, even when a very low degree of heat was used, and with or without salt. A Howell furnace gave somewhat better results, although it did not chloridize very well, yet it did not spoil the ore for further treatment in a reverberatory furnace, and a furnace of this class was therefore connected with the ore chamber of the Howell in such a manner that the ore could be transferred to it from the chamber at stated intervals and the roasting completed. Two per cent of salt was crushed in the battery with the ore, and two per cent was added in the reverberatory. In this way, with careful management of the heat, fair results were obtained. Mr. Hoffmann says: "If the roasting is properly conducted, the blue flame of the ignited pyrites can be observed in the back part of the cylinder. Next to it, and reaching beyond the middle of the cylinder, the ore assumes a higher temperature, forming a belt of bright-red heat. The part of the furnace next to the fire and nearly one third of the whole length has to look dark. The furnace is mostly heated by the combustion of the sulphides and receives but little supply from the fireplace and from the reverberatory. In fact, the ore while in the cylinder should be left as much as possible to roast in its own heat. This is a very important condition to maintain. The object is to convert as much as possible of the galena and zinc blende into sulphates and oxides before generating chlorine, and to avoid until then as much as possible the decomposition of the iron salts. * * An excess of heat is invariably connected with an excessive loss of silver by volatilization and by a low chlorination. Galena and zinc-blende roast quicker and better in a low than in a high heat. When the ore leaves the cylinder and drops into the pit, it should be of a very dull red heat, while the color, after cooling, should be dark yellow-brown.

"When the properly prepared ore enters the reverberatory furnace the salt is added and the temperature increased. It commences to fume, and swells without forming more lumps than an ordinary ore. In the beginning strong fumes of sulphurous acid emit, but soon cease, and chlorine appears."

The capacity of the cylinder, 24 feet long, and the connected reverberatory was only 8½ tons of ore in 24 hours, owing to the refractory character of the ore.

The assorted ore contained:

	Per cent.
Zinc	25.50
Lead	11.56
Iron	6.50
Manganese	0.53
Cadmium	0.30
Antimony	0.52
Copper	1.02
Alumina	3.65
Calcium carbonate	8.00
Sulphur	21.01
Silver	0.12
Gold	trace
Gangue, insoluble	19.41
Total	98.12

A little nickel is given in the analysis of a sample of unsorted ore.

It was found that coarse crushing would not answer for this ore, a 40-mesh sieve giving better results than a 20-mesh, while the difference in the quantity crushed per day by 20 stamps was only 7½ per cent in favor of the coarse screen.

Speaking of crushing-rolls, as compared with stamps, Mr. Hoffmann says: "Rolls produce a pulp more uniform in size, and a much larger percentage of it corresponds in size with the size of the meshes of the revolving screen. Now I found that in order to chloridize well the Del Oro ore had to be crushed through battery screen No. 40, which furnished a pulp, of which only 9½ per cent was coarser than in sieve No. 90. * * * Such fine crushing is necessary for certain ores, and it is, therefore, not prudent to recommend or adopt rolls regardless of the nature of the ore."

The last remark is simply common sense; it will not do to generalize from particular cases, and much mischief has been caused by the adoption of machines and methods under conditions to which they were not adapted. In the Del Oro ore the greater part of the silver is in the blende; blende does not decrepitate in the roasting and the larger portion of it remains in the form of sulphate, not being chloridized unless a very large proportion of salt is used; it is, therefore, important that the silver mineral which is inclosed by the particles of blende shall be exposed by fine crushing. Where blende merely accompanies, not incloses, the silver mineral, the case is different, and coarser crushing may answer. With galena inclosing silver sulphide the case is again different; it decrepitates in the heat, which answers the same purpose as finer crushing. The same reasoning applies if we suppose the silver mineral to be combined instead of simply inclosed in the other, but this is perhaps doubtful; silver glance can be separated from argentiferous galena by grinding with potassium disulphate, which converts the galena to sulphate with evolution of H^2S.

Mr. Hoffmann calls attention to the fact that the proportion of soluble silver is often increased by the action of the base-metal chlorides during the washing of the roasted ore, especially when copper is present; or by allowing the ore to remain some time in a moist state, when that is allowable before the leaching. In the present instance the ore is not moistened prior to leaching, because of the caustic lime which it contains, but it is dumped while still hot into the leaching-vat containing some water, and a better result is obtained if that water is charged with bluestone and salt in the proportion to make cupric chloride; the gain in silver solubility in badly roasted charges is as much as 34 per cent.

The Sprague Electric Railway.

The following is an extract from a letter from F. W. Nickerson of Boston to A. A. Nickerson of San Francisco, referring to electric railways: "The overhead system of electric railways is very successful here in the East, and is in every way cheaper to run and build. Make this suggestion to the company. I think they will knock out cable roads, elevated, horses, etc. They can run them 12 and 15 miles an hour and stop them in a short distance; can carry two cars as well as one, and run almost noiselessly. They are even a fair success with the underground wires, but are not up to standard, compared to overhead ones."

This letter is from the city where the Sprague Electric Motor Co. has one of its most important roads. This company has made wonderful progress in equipping mines as well as railways with electricity in the last year and a half. The mining plants at Aspen, Colorado, are not sole examples.

It is to be hoped that Mr. J. L. Jayne, 328 Montgomery street, in this city, who is the agent here of the company, can, through his familiarity with the subject and designs in his office, show our people the advantages of electric transmission.

The following paragraph, from the St. Joseph *Daily Gazette*, is of interest in this connection: "It should be a matter of pride to the citizens of St. Joseph that they are possessed of this electric railway, for, to say nothing of the material benefits accrued to the citizens by the increased service of the road, it is a very good advertising medium for our city. Nearly every day some gentlemen are in St. Joseph from some other city to investigate the Sprague system, and they come from all quarters of the United States. Yesterday a gentleman from Portland, Or., was in the city for that purpose, and several days ago one from San Francisco on the same errand."

CŒUR D'ALENE MINES.—The expected prosperity of every district of the South Fork and the growing interest taken in all parts of Cœur d'Alene makes this favored section indeed the land of promise. Most interesting developments have been recently made in some of our best mines, and prospecting work continues, proving and opening encouraging extensions to the great ore bodies already known to exist. All operations in mining are most systematically carried on and no desire exists to establish a fictitious reputation, but every effort is made to keep all transactions connected with our mining interests within the realms of common sense. We are at the opening of what cannot fail to prove a most profitable mining season. We are in the heart of a great and growing country, and there is not a more progressive community to be found in the Northwest than the resolute miners of Cœur d'Alene.—*Wardner News.*

Mossbrae Falls.

We present on this page a photo-facsimile of a scene of rare natural beauty and of exceptional interest in the peculiar methods of Nature's work which it embodies. The scene is situated in the Mt. Shasta region and lies very near the Upper Soda Springs. The observer will say at first glance that it is a waterfall, and such of course it is, and yet not what is commonly implied by the term, for one would search in vain upon the summit of the bluff for the stream which is usually the parent of the waterfall. Waterfalls without apparent source are common in the Shasta region. Their sources, their methods and their beauties are charmingly described by John Muir in one of the later parts of his "Picturesque California" as follows:

"Only a very small portion of the water derived from the melting ice and snow of Shasta flows down its flanks on the surface. Probably 99 per cent of it is at once absorbed and drained away beneath the porous lava folds of the mountain to gush forth, filtered and pure, in the form of immense springs, so large, some of them, that they give birth to rivers that start on their journey beneath the sun, full grown and perfect without any childhood.

"This flat current, issuing from horizontal seams in the face of the wall of the river gorge, in one unbroken sheet flows in a lacework of plashing, upleaping spray over bowlders that are clad in green, silky algæ and water-mosses to meet the smaller part of the river, which takes its rise higher up. Joining the river at right angles to its course, it at once swells its volume to three times its size above the spring. The vivid green of the bowlders beneath the water is very striking, and colors the entire stream, with the exception of the portions broken into foam. The color is chiefly due to a species of algæ which seems common to springs of this sort."

Such grand springs are frequent in the Shasta region. Sometimes one hears their sounds long distances. Sometimes he comes upon them almost unawares. Speaking of one in particular, Mr. Muir says: "The Big Spring of the Sacramento is about a mile and a half above Sissons, issuing from the base of a drift-covered hill. It is lined with algæ and mosses, and shaded with alder, willow and thorn bushes, which give it a fine setting. Its waters apparently unaffected by flood or drouth, heat or cold, fall at once into white rapids with a rush and dash as if glad to escape from the darkness to begin their wild course down to the plain."

These beautiful descriptive lines by Mr. Muir will add to the interest of our engraving, and will give an intimation perhaps of the treasures of the Shasta region and of our other mountain districts. Railways and improved carriage-roads are making these places more accessible. Our agriculturists should not allow these resorts to be enjoyed alone by foreign tourists and city campers. The proposed excursion of Californians to attend the meeting of the Oregon State Grange, if carried out, will lead many to acquaintance with the Shasta region. In nearly all parts of the State there are romantic spots which can be easily reached by wagon, to which the family can be taken for a restful outing this summer. Let them all be enjoyed. With a good outfit of team and wagon and camp equipage, a family can cheaply enjoy an excursion, covering many miles of distance.

MOSSBRAE FALLS, NEAR UPPER SODA SPRINGS, IN THE MT. SHASTA REGION OF CALIFORNIA.

CEMENT GRAVEL.—The Placerville *Observer* says: Mr. S. K. Snodgrass of New York was in this city and vicinity during the past week, looking after mining interests. Mr. Snodgrass is the representative of a machine for the working of cement gravel, for which great results are claimed. This machine is not intended as a crusher, but to dissolve the cement, cleaning the cobble-stones, leaving the gold free and easy to amalgamate. We hope this gentleman may find a favorable place to put up one or more of these machines. It is represented that they will work 150 tons per day, with about four-horse power.

MINERAL WAX.—The first carload of mineral wax, a substitute for beeswax, and which will be largely used by electricians, recently arrived in New York. It is called ozocerite, and is found about 414 miles east of Salt Lake City, where there is the only source of supply yet known, except in Galicia, Austria. Ozocerite contains from 85@95 per cent of pure wax. Its color varies from a light yellow to dark brown or black. It requires from 160 to 190° Fahrenheit to melt it, and it is claimed to be the best insulator known. It possesses the greatest resistance to an electrical substance and is acid proof. It has been used by blacking manufacturers and in the manufacture of sealing wax. When it is refined it is called ceresin, and can be used just as beeswax is used. It costs just one-third as much as beeswax. Candles and dolls can be made with it.

MT. WILSON OBSERVATORY.—The Harvard 13 inch telescope has been delivered on Mt. Wilson. A temporary observatory building is to be erected at once, and the work of photographing the northern heavens begun. The office of the United States Signal Service will be moved to Mt. Wilson. At a meeting held at the Carlton hotel, M. M. Bovard, President of the University of Southern California, stated to a prominent citizen of Pasadena that he expected the city to build a wagon-road to the summit of the mountain, and donate real estate for an endowment fund to pay the running expenses of the great observatory to the amount of $100,000.

REWARDS FOR INVENTORS.—The Committee on Science and the Arts of the Franklin Institute of the State of Pennsylvania has been empowered to award or to recommend the award of medals for meritorious discoveries and inventions which tend to the progress of the arts and manufactures. These medals are the Elliott Cresson medal (gold), which was founded by the legacy of Elliott Cresson of Philadelphia and the John Scott legacy premium and medal ($20 and a medal of copper). They will be awarded to ingenious men and women who make useful inventions, or for some discovery in the arts and sciences, or for some new process in combination of materials in manufactures, or for ingenuity, skill or perfection in workmanship. Upon request from interested parties made to the secretary of the Franklin Institute, full information will be sent respecting the manner of making application for the investigation of inventions and discoveries, and the Committee on Science and the Arts will receive and give consideration to reports upon discoveries and inventions which may be sent to it.

Clay Selvage.

The Virginia (Nev.) *Enterprise* says: In mining litigation the formation of the clay selvage found upon the footwall of a vein, or floor of the formation, is often debated. Days are often spent in the examination of witnesses to prove that the clay selvage found in the ground in dispute is the genuine boundary-wall of a vein, while the opposing side may strenuously contend that it is nothing but the result of the seepage of surface-water through cracks in the diorite formation. The action of the water on the diorite carries particles of the rock and deposits it on any wall or floor that will hold it, forming a clay selvage.

"It is very easy to tell this character of clay from the genuine deposit of clay which is made in the formation of a vein," said a well-known mining man yesterday. "I have learned to distinguish it by experience, and I defy any one to put me to the test. If it is gritty, it is formed by the action of the surface-water; if it is soft to the mouth as dough, it is the genuine article, and was formed by the action of steam or vapor rising from the depths and carrying in solution atoms of the country rock through which it passed, and as the vapor ascended to the surface and cooled off, it gradually precipitated its contents."

THE SAN PEDRO WILL RUN.—The report that the celebrated San Pedro (N. M.) copper mine would close down on the first is emphatically denied by the management. The rumor was first started by persons who have evil designs upon the present management, who secured the property from the prior owners after a long siege of litigation in the courts of the Territory and the U. S. Supreme Court. The company is constantly increasing its force, and is sinking an immense well to secure water to start up another furnace. Over 500 miners work on the big copper mine.

THE city of Oakland is endeavoring to obtain from the Government about 70 acres of the north arm of the harbor to create a flushing basin for the great intercepting sewer which is to be built along the whole water-front and out into the bay.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ZEILE.—Amador *Ledger*, March 30: The sinking of the Zeile shaft was finished this week. The shaft is now 1160 feet deep. The lowest level is 1075 feet, with 85 feet of sump below. From 25 to 30 stamps of the mill are kept running. By the 1st of May the 40 stamps will all be running. The French company that have bonded the cement gravel claim at Volcano have struck the pay channel. While the cement is no doubt rich, still the question is whether it can be made to pay by a company after paying $10,000 for the property, and spending an equal amount in the erection of a stamp-mill. The cement is of the hardest description, far worse to get out than the hardest kind of quartz. It cannot be blasted, but has to be picked out. Operations have been commenced on the Morley or Wetzlar claim in Hunt's gulch. The shaft of the Alpi is now down nearly 40 feet. The water is no longer difficult to manage. The ledge commences to turn to the east. The Amador gold mine paid off last Friday, on the return of the superintendent from San Francisco. It is reported that A. P. Minear, who is in London, is confident of making a sale of the property to an English syndicate.

Calaveras.

THE SWANK QUARTZ MINE.—*Prospect*, March 29: The following in regard to the Swank mine is interesting, as it shows there is plenty of gold in Calaveras if it can only be located. The immediate footwall appears to be a porphyritic slate. All of the indications connected with this vein, and the vein itself, give promise of its being a rival of the Sheep Ranch mine, in the near future. The Swank quartz vein is in a belt of rich mineral-looking blue or manganese slate, which is two or three miles wide, and no doubt the careful prospector will find that there is more than one rich quartz vein in this belt that will prove to be the equal of the one recently discovered by the Swank brothers. The discovery of this rich quartz vein and many others in Calaveras county during the 80's is proof most positive that the quartz mines of our county are hardly prospected yet.

Contra Costa.

THE INDEPENDENCE TO START UP.—Martinez *Gazette*, March 30: For some months it has been a known fact that steps were being taken by Mr. James Rankin to put the old Independence shaft at Somersville in working order, but the obstacles in the way were great, and it has been deemed best by those concerned to keep the matter as quiet as possible; but nevertheless the work of placing machinery, erecting a hoisting works, and other details have been going steadily along, until the mine is almost ready to start up. Last week steam was gotten up as a trial of the new machinery, which had been set up by Hamilton & Clair, and the trial proved satisfactory beyond expectation. It is now some 13 years since the mine was worked, and to say that the sight of steam and the sound of machinery at the old shaft was welcome to the coal miners of Somersville is wholly unnecessary. The shaft is down some 700 feet, 500 of which depth is supposed to be filled with water, which will have to be pumped out before the work of taking out coal can be commenced. A splendid vein of good coal is known to lie at the bottom of this mine, and when the water is once removed can be taken out very easily and in very large quantities. This vein is known as the Clark vein, and is said to be the best known in the Mt. Diablo district. It is expected that the mine will be freed from water in less than two months time, when the work of cutting coal will be commenced.

Fresno.

GRUB GULCH. — Mariposa *Gazette*, March 30: Last week we visited the lively little mining camp of Grub Gulch in Fresno county. We found the place fairly bubbling over with life and prosperity. Grub Gulch has some very valuable mines, and the five mills at the Josephine and Haley mines are daily proving that there is plenty of gold yet in Fresno's hills. There are numerous rich veins all through the mountains and gulches, and paying strikes are constantly being made.

Inyo.

NO GO.—*Register*, March 29: Messrs. Boland & Gorman, lessees of the Union mine at Cerro Gordo, have had notification that the Reno reduction works will not receive any more of the dry flue dust concentrates, which was being taken from the dump of the old Beaudry furnace. The efforts of these gentlemen to get the silver out of this stuff have been hard and costly, and the present result is a little hard again.

SOLITARY. — The Reilly mill, Slate range, is watched by Wibbelt, a lone old guardian. J. D. Channel's comparatively new mill at Wild Rose is destitute of population and supervision of even one man. Coleman's big borax works in Death valley has, during the past winter season, had occasionally two, but now has only one sweltering individual to guard its collapsed greatness. Jerry Fitzgerald wrestles alone with the horn silver ores of Lee district.

CERRO GORDO.—Geo. Weirt, with his two partners in the lease of the famous Ygnacio at Cerro Gordo, is doing well. They are working an 18-inch streak of yellow chlorides, which assay 200 ounces of silver per ton, and in itself is an entirely new feature to those familiar with the property in "auld lang syne." Hawley, the owner, gets the enormous rental of 25 per cent of the profits.

Los Angeles.

A STRIKE IN THE MIDDLE RANGE.—Pasadena *Union*, March 29: There is a rumor on the street this morning that another rich find has been made on the Wilson trail. Ed Durfee left this morning for his mines in the Placerita canyon near Newhall. Charles Marsh came in this morning from the Silver Reef country with a quantity of fine-looking ore, which came from some place in the Blackhawk range. It contains considerable lead and iron and doubtless considerable of the more precious metal. Some very rich float rock was being displayed on the street this morning. Free gold is becoming plentiful. Johnnie Mills feels elated over the new finds in which he is interested. The placer miners are still panning out the yellow metal at various places along the foothills. Mines must take the place of real estate to give our business life a new impetus.

THE QUARTZ-MILL.—Los Angeles *Herald*, March 27: Edward Dunham and Stanford Johnson, who are about to erect the quartz-mill in Newhall district, have returned from their trip up north. Mr. Dunham showed a *Herald* man yesterday a dispatch from the agent at Newhall, stating that the machinery for the mill was on the ground, and would all be in position inside of 20 days. A 30-stamp mill, the largest of the Huntington make, is to be erected about 12 miles above Newhall, in the San Francisco canyon. This will induce a great deal of prospecting, and as that part of the country is undoubtedly rich in mineral, some satisfactory results are expected.

Mariposa.

RIBBON ROCK.—Mariposa *Gazette*, March 30: C. A. Schlageter showed us some samples of rock from his mine last Tuesday, which shows the excellent quality of the vein. The rock is what is known as ribbon or layer-rock, and shows gold in every seam or crevice. It is the best kind of milling ore, for although it does not show the gold in big nuggets, the precious metal is distributed thickly all through it and will mill to big advantage. They have not gone in very far yet, but the vein widens as they proceed, and beyond doubt they have a good mine.

Napa.

VALUE OF THAT BULLION.—*Calistogian*, March 27: We have been asked several times the value of the bullion shipped from here a few days ago, and produced at the Palisade mine. We cannot state the value, though we probably could have learned the figures, but not for publication. The bullion contained more or less gold, and was probably worth $8000. This is merely a guess, as the amount of gold in it we do not know. The gold may have increased the bullion's value a thousand or two more. The owners of the mine are not a corporation. They transact their business as a company engaged in any other work do. They are not inclined to tell the secrets of their work more than any other company; but they are making money and are entirely satisfied. They have got a mine that will keep them busy many years.

A DIVIDEND.—There are many mines that afford a fine profit for the owners, as does the Palisade gold and silver mine near Calistoga; but stock mining companies in California that pay dividends are comparatively few. Among these is found one in Napa county, viz., the Napa Consolidated quicksilver mine in the Oat Hill mining district, which is successfully superintended by B. M. Newcomb. The company has paid numerous dividends, and April 1st next it will pay another—$10,000, or 10 cents per share on its capital stock. The mine continues to look promising.

Nevada.

MINE ATTACHED.— *Tidings*, March 30: A Wheatland rancher named D. N. Jones attached the Golden Jacket mine at Cabbage Patch, near Spenceville, last Thursday. Jones claims to be a creditor to the extent of $1200, for material, labor, etc. There is $20,000 worth of machinery on the mine, which is owned principally by the Farmers' Union of Livermore. We understand that negotiations for the sale of the mine have been pending, the property being looked upon as promising by practical miners. The Livermore Grangers were financially crippled in providing the machinery.

AN INSOLVENT MINING CO.—*Tidings*, April 3: In the Superior Court this afternoon an order was made on petition of the stockholders of the company, adjudicating the Green Mountain Consolidated Mining Co. of Grass Valley to be insolvent. The liabilities are placed at $12,213.43, and the assets comprise the company's mine, $1300 in ore and bullion, and a hoisting and pumping plant. There is a mortgage of $400 on the machinery, however. The majority of the items of indebtedness are for labor, and range from $2139.75 to $3. The creditors named number 71.

Placer.

DUTCH FLAT.—Cor. Placer *Republican*, March 30: A movement is on foot to prospect for drift mines here, and a paper is being circulated to see if enough money can be raised. The plan is to sink a shaft in the ravine below town on the shallowest part of the supposed channel, and prospect it thoroughly.

Plumas.

BUTTERFLY DISTRICT.—Plumas *National*, March 30: We are indebted to D. M. Hambly for the following mining news: Thompson, Smith & Co., in the Butterfly district, at present are not working many men underground, but getting ready for spring work. They have one of the best prospects in this county, both in quartz and gravel. They have started a new shaft on the quartz and are down about 40 feet. Free gold can be seen in the quartz as it is raised to the surface. Another prospecting company in the same neighborhood has struck very rich prospects, both in quartz and gravel, which they are developing quite satisfactorily. Orr, Bushman & Co. are under headway in developing their mine, with very flattering results as to the paying qualities of their plant. Music & Sholfer take their time to clean up, but it is always there just the same. John Higgins has just commenced to ground-sluice, since the rain.

Shasta.

NOTES.—Shasta *Democrat*, March 29: The Calumet mill will start up about the first week in April. We are told that negotiations are pending for the sale of the Gladstone mine on Cline gulch. The Calumet company is putting in a low-pressure Knight water-wheel for running their new plant. The new mill and furnace of the Calumet company is about completed. The new plant is located 400 feet south of their 24-stamp mill, and is intended for working their sulphurets and richer ore. Last Friday five bars of bullion from the Lost Confidence mine were brought down and shipped to the Argo smelting works. The proportion of gold in the bullion has increased of late 20 per cent, so we are informed. Cummings & Osborne, owners of the Gladstone mine on Cline gulch, brought down an $8000 gold brick last Saturday. This is the cleanup from plates and battery for a 30-days' run, and a handsome one it is. The Cline Gulch mines will undoubtedly develop into another Deadwood. Last week Fred Ten Eycke sold the old Black Rock claim, situated between Spring creek and Boulder creek, to James Salla of the Lost Confidence mine, for $1000. Fred relocated the claim the first of this year, it having formerly been owned and prospected by Bud Levens of Oakland, Jim Campbell and Lee Fader of this city.

FROM KENNET.—A large crowd of men is kept busy at the Uncle Sam mine repairing damages done by the late rainstorm. The Clipper Mining Co. is only working a small force at present. A new five-stamp mill will be erected on this fine mine this spring. The Snyder mine is not being worked at present, but operations will be resumed shortly. The Shasta Bell Mining Co., D. B. Grant manager, is running tunnels, and the prospects are that some good mines will be opened by this company in the near future.

THE SIERRA BUTTES MINING CO., to which concern Jack Conant disposed of his Uncle Sam mine for $150,000, is making rapid headway constructing a wagon-road from Kennet to the Squaw Creek mines. When the road is finished, the number of stamps in the company's mill will be doubled, and before the summer is over it is understood there will be 80 stamps pounding away on the rich ore of the Uncle Sam mine.

Sierra.

AT THE SIERRA BUTTES MINE.—Sierra *Tribune*, March 29: Last Monday 40 men who were working in the Sierra Buttes mine were drafted by the company. Twenty stamps were "hung up" at the 60-stamp mill below town. It is said that there is likely to be several more men discharged in a short time. This is very unfortunate for Sierra City, but a mine cannot be expected to run 250 men forever. The Sierra Buttes is probably the oldest mine on this coast, it having been worked already over 30 years. But by no means does the discharging of a few men show that the mine is not good for five years more anyway. There are 160 men on the pay-roll now. Twenty stamps are pounding away at the mill daily up at No. 6, while there are 40 stamps running at the lower mill. Among the 40 men discharged only two are married, the rest being single men. It is said that 20 stamps will soon be added to the mill on the hill, making it a 40-stamp mill.

POCKET.—*Mountain Messenger*, March 30: M. Harp found a quartz pocket, last week, on the Chips' side of Kanaka creek, and pounded out $600 with a hand mortar.

MORE STAMPS.—Messrs. Onstott, Hoskins and Mosher came up from Nevada City last Monday, to the Red Chief mine on Kanaka creek, near Alleghany, to put 20 more stamps in the company's mill, which already has 20 stamps.

TUNNEL.—Mammoth Springs' tunnel, above Forest City, is in 1500 feet. The rock is soft picking, and gravel expected at about 500 feet ahead.

Santa Barbara.

BEACH MINING.—Lompoc *Record*, March 30: A company, with W. S. McKay at the head, has been formed to work the beach mines on a grand scale. Steam-power will be used to raise the water of Bear creek to the flume, and it is expected to put through from 50 to 75 tons of sand per day. Mr. Heller has gone to S. F. to procure the latest machinery and processes for saving fine gold. We shall watch the operation of this company and note results each week. The parties so far, working with the crudest methods, have taken out several pounds of dust and shipped it to San Francisco. Sufficient inducement is given those working the mines for the past month to justify, in their judgment, quite an expenditure to see what can be accomplished on a large scale.

Tulare.

PLACERS.—Tulare *Times*, March 28: Supervisor James Barton returned from the Rattlesnake creek mines, 25 miles east of this city, on Tuesday evening and brought down some samples of gold ore now being mined there, for assay. The lead has been traced for three miles, and 13 claims have been located, only a few of which are being worked at present. He says all the earth in that section contains more or less gold, and if there was water handy, from $2.50 to $5 per day could be made at placer mining. But there is no water to be had at a reasonable distance from the mines except during the rainy season. Many old miners have visited the district and all speak favorably of the developments in the quartz leads.

Tuolumne.

NEW ALBANY.—Tuolumne *Independent*, March 30: The rich shoot of ore struck in the New Albany, some two months ago, still continues, and enough of this bonanza rock is now in sight to feed a 10-stamp mill for a year. The vein is opened 100 feet from surface, and shows a pay shoot of 150 feet. They are now crosscutting 300 feet from the former crosscutting.

GOLDEN GATE.—It is the intention soon, so Mr. Long informs us, to put up chlorination works at the Golden Gate; not only to treat their own sulphurets, but also of capacity for custom work. This will be a great convenience for our mining friends, as they are compelled to send them below, at large expense.

PROSPECTING.—*Independent*, March 30: Prospecting promises to develop into a perfect boom this spring. The gold taken from the celebrated Bonanza has been heralded far and near, and already feverish miners are drifting into this section in search of pockets. Tuolumne gold is no myth—it is a true El Dorado—and people are beginning to find it out.

THE Tom Whitto quartz mine, Jacksonville district, would turn out a bonanza for a strong company. The vein is 150 feet in width, the ore prospecting from $3 to $7 per ton, with places much richer. It has been splendidly developed for the past six years, and is now in good condition to show its great value.

BUCHANAN.—In the Buchanan mine, the ore is showing up rich from the lower levels, and the mine is looking well, the owners being well satisfied with Supt. S. B. Moore. Fifty men are employed.

GOOD ORE.—The Eureka quartz mine, at Summersville, is turning out some very good ore, and the outlook is very promising.

NEVADA.

Washoe District.

INDUSTRIOUS PROSPECTORS.—Virginia *Enterprise*, March 30: Virginia is filled with idle men; but they are not all positively idle. The old miners and prospectors who have been with us many years, while waiting for steady employment, engage their knowledge and experience meanwhile at prospecting in the hills to the north, west and south of the great lode. They take a little prospecting pick, with hammer attached, and with a light lunch and pipe and tobacco, they roam the hills, carefully inspecting float and chipping off pieces of rock here and there as thousands have done before.

HALE & NORCROSS.—On the 400 level have commenced stoping ore from the south drift from joint west crosscut on our north boundary. The ore is of good quality. On the 500 level the south drift is now advanced 200 feet and has reached our south boundary. The north and south upraises have been advanced 10 and 15 feet respectively, and continue in excellent ore. On the 600 level are extracting the usual quantity of fair grade ore from the several stopes. On the 1300 level west crosscut No. 1 has passed through 12 feet of old fillings, and have commenced extracting ore from the old stopes. During the week have hoisted 810 tons of ore and have shipped to the Nevada mill 817½ tons, and have milled 784 tons; average battery assay, $25.09.

CHALLENGE.—The north drift on 1200 level has been advanced during the week 16 feet; total distance, 46 feet. The face shows vein material. The joint Challenge-Confidence east crosscut on the 1300 level is now out 17 feet, 12 feet having been added during the week; the face shows vein material. The joint Confidence-Challenge east crosscut from the north drift on the 300 level is out 30 feet, 13 feet having been made. The crosscut passed through four feet of fair ore and the face is now in vein material. The same level is out 80 feet, 12 feet having been made during the week. The face shows barren quartz.

SAVAGE.—On the 400 level are stoping ore from No. 1 and No. 2 southwest crosscuts; the ore is narrow but of good grade. From the north drift on this level are extracting ore from the old stopes. On the 500 level the upraise from No. 3 west crosscut is now advanced 75 feet; the face is in low-grade quartz. From the south drift on this level are extracting ore from the old stopes, also from No. 3 east crosscut, 600 level. During the week have hoisted 619 tons of ore, have shipped to the Rock Point mill 527 tons, and have milled 505 tons; average battery assay, $22.

ALTA.—The mill running steadily from ore on the 800 level and stopes above the 825 and 955 levels. Are upraising in fair milling ore on the 925 level in a body from 10 to 11 feet wide. The upraise on the 725 level is up 370 feet. Crosscutting will commence 30 feet further up to connect with the workings on the Keystone ledge. Thorough crosscutting and prospecting will also be done above that point.

BELCHER.—The 200 east crosscut is in 98 feet and the face in quartz and porphyry. The 200 west is in 77 feet, the face in quartz and porphyry with bunches of ore of fair assays. The 100 east is in 100 feet, face all porphyry.

OVERMAN.—Extracted 272 tons of ore; shipped to the Vivian mill 318 tons. Have done considerable repairing in the main drift, timbering, relaying track and turntables. Stopes in mine yielding the usual quantity of ore.

CHOLLAR AND POTOSI.—The regular work of exploration is progressing. Are now crushing only 30 tons of ore daily, by reason of the Hale & Norcross using 30 of the 40 stamps in operation at the Nevada mill.

CONFIDENCE.—Have shipped during the week to the Brunswick mill 653 tons of ore, the average samples of which show a value of $31.12 per ton.

JUSTICE.—Crosscutting on the 500 level and extracting about 30 tons of ore daily of the average value of $21 per ton.

CROWN POINT.—Continue taking out ore, and have shipped to the mill during the week 912 tons and milled 875 tons.

BALTIMORE.—Prospecting on the 338 level to the northward and saving up some good ore for reduction.

CON. IMPERIAL.—Some necessary repairs to the main north lateral drift are still being carried on.

BULLION.—No change to report in the work below the 500 level.

ANDES.—Drifting northward on the 175 level.

Eureka District.

PROSPECTING.—*Sentinel*, March 30: Prospecting in the outside mines of this district, it is said, will be very lively this summer. Eureka is not dead yet. All the teams hereabouts will now be employed in hauling ore from the mines to the furnaces for some time to come. Messrs. Langton, Allen and Shine have a lease of the Oregonian mine. They have struck a fine streak of very rich ore in it and are making money. It is now an assured fact that the smelting companies will commence buying ores next Monday. This is good news for the miners and the balance of our people.

Hawthorne District.

THE NEW BOUNDARY.—Walker Lake *Bulletin*, April 3: The boundary lines of Hawthorne mining district are: Commencing at Kincaid; thence running south to Modoc Springs; thence southerly to Excelsior Flat; thence southwesterly to Antelope Springs; thence northerly to the 105-mile post on the C. & C. R. R.; thence along the line of said road to the place of beginning.

Sylvania District.

A SALE.—Esmeralda *News*, March 30: Andy Fife, who has been experting mines in the southern part of the county in the interest of Walter E. Dean of New York, has purchased a group of mines in Sylvania mining district. The price paid was $25,000. The ore in the mines purchased carries a high percentage of lead, and is rich in silver. Mr. Fife and the purchaser are now at the mines, and work will be commenced thereon immediately. Capital is something that has been lacking in the southern end of the county, and now that it has been forthcoming, big things are expected. The people in that section are jubilant over the prospects.

Tuscarora District.

FOUND TREASURE.—Tuscarora *Times-Review* March 29: Preparations are being made to put in a tank at the 200-foot station.

COMMONWEALTH.—150-foot level: No. 3 winze has been sunk and timbered 2 feet. The bottom

still in very rich ore; will not do any more work in the winze until connection is made from 225-foot level. The No 2 east lateral winze has been connected with 225-foot level, and drifts started north and south, showing good ore both ways.

NORTH BELLE ISLE.—North drift, 300-foot level, extended 8 feet. The water has been very strong for the last few days, causing some delay. Air boxes have been put in, which materially assists the ventilation. Will start hauling ore to the Union mill on the 30th inst. The stopes throughout the mine are looking well.

NEVADA QUEEN.—Tramway to the mill is about completed, ore bins finished and the mill will start Monday morning. At the concentrator everything is running nicely; average assay for the week $17 08 per ton, working to 83 per cent. The stopes are about as last reported, yielding 200 tons for the week.

GRAND PRIZE.—300-foot level: East drift from north crosscut extended 20 feet in low-grade ore. West drift from north crosscut extended 18 feet, face shows some improvement. South drift extended 12 feet. The vein continues strong, but the ore is low grade.

NAVADO.—The stope from No. 5 upraise looks well and is turning out some fine ore. The stopes throughout the mine are looking well and the usual quantity of ore has been sent to the mill.

BELLE ISLE.—West crosscut, 250-foot level, extended 18 feet and the face is in light-colored porphyry.

ARIZONA.

TOO MUCH WATER. — Cor. Prescott *Courier*, March 28: Last Saturday night the water burst in at the face of the tunnel, belonging to the United Verde Copper Co., about 900 feet from the mouth, and run their men out, filling the tunnel with sulphurets and sediment, and running down the gulch from six to eight feet high, carrying log rocks and an anvil with it. It caused a cave from the surface, carrying down dirt, slag, slag-pots and wood, and cracked the earth back as far as the company's smelter. The smelter started last Wednesday, and has been running quite successfully under the superintendency of J. L. Thompson. The stream which flowed from the water-strike filled a canyon 40 feet wide to a hight of 10 feet as it rushed Verde-ward.

CARBONATE ORE.—G. W. Hull and H. C. Blackford have struck a body of carbonate ores, about 700 feet west of the United Verde Copper Co.'s works, which bids fair to be one of the best mines of the camp. It is called the Lucky Boy mine. They contemplate shipping from five to ten tons of ore in about three weeks for a test. E. H. Witherell will start his teams to hauling coke and matte this week.

COLORADO.

REVIVAL.—Elk Mountain *Pilot*, March 30: We are on the eve of a substantial mining revival. Last year there was a great deal of talk about what was going to be done, and in the end very little was done. This year we have strained an ear in every direction to find out what new enterprise would be started, and while we have heard but little, it all seems to sound like business. In another month we expect to record some cheering news in the way of mine development. Earnest inquiry is being made after mining claims that have been idle for years, showing that the owners have not entirely forgotten them. With the present state of weather we are bound to have the earliest season ever known in this country, and there is nothing to prevent any of the mines from commencing work at once. S. C. Robinson at Pittsburg will take advantage of the season and start his concentrator next week. He completed a ten-ton concentrator last fall, to run by water-power, expecting to run all summer. We do not know or hear of any other properties in Poverty gulch that are going to be worked, although such mines as the Excelsior, Jacob Straeder, Hawkeye, and several others we could name ought to be worked. They have got the mineral, and it is not taken out.

DAKOTA.

FLOAT.—Black Hills *Pioneer*, March 30: The report sent out early last week from Big Sandy, Mont., giving an account of gold excitement in the Sweet Grass hills and that such large numbers were flocking to the new fields as to seriously threaten a famine, was made out of whole cloth. The Sweet Grass placers have been worked for a number of years, and while considerable gold has been and is being taken out, there has been no unusual rush to the hills since 1878. The hills are located on the recently opened Piegan reservation, and while they are believed to be rich in minerals of all sorts, they have never been thoroughly prospected. The Seabury-Calkins is now working a force on ore of excellent quality. Shipments to Omaha have been made at intervals, and will continue regularly for the future. Good reports continue from the Spanish R. The recent strike, before noticed, has proven fully as important as was expected.

IDAHO.

PLACER MINING.—Idaho City *World*, March 30: Placer mining has been going on quietly a few miles from this place, when everybody was predicting that the season would prove a total failure, and hydraulic chiefs would have a rest until next spring. The Traverso boys have been piping about ten days. They reservoir the water and work only in the daytime. Brockmiller, Cetovitch and Reagan have been piping a week, having commenced a week ago yesterday. They are also reservoiring—hoarding up a supply of water at night and turning it loose to do its work daytime. A Chinese company has been at work for some time in a placer claim between this place and the Warm springs. The season will not be so poor, after all, as the prophetic predictions have pictured. If storms continue during the spring and early summer, which is not at all an improbability, as we have had dry weather for a year, mining will continue just the same as if the regular depth of snow had fallen during the winter.

RICH ROCK.—The 36 tons of Washington gold-bearing ore recently crushed in the Forest King mill, turned out more than the estimate given in last Friday's *World*. Before melting it was thought to be between $5000 and $6000, or something like $150 per ton. It runs up to $6193.03, making $172 per ton.

LOWER CALIFORNIA.

SANTA CLARA CAMP.—Cor. S. F. *Chronicle*, April 1: About 2000 miners are in the camp now, but they are leaving by the hundreds, and in a month there will probably be not more than 300. The placers are an admitted failure, but some prospecting for quartz ledges is being done. The best day's work for two men that I have seen was $14, taken out on a claim owned by a man named Cochrane, though several Indians have done well. There were about 25 claims here that a man could make wages on, but the greater part of them are worked out, and unless the International Co., which has a dozen or more men prospecting the hills, can get up a new excitement and get the gold-seekers farther down the peninsula, I am afraid everybody will leave in a short time, as provisions are so high that not more than half of them have money enough to stay over two or three weeks at the longest. Every day there are long lines of men with their blankets on their backs coming into Ensenada from the mines on their way back to San Diego, sadder but wiser men.

GOLD.—Cor. San Diego *Sun*, March 28: In your columns the disappointed have stated that there was a little gold at Santa Clara on the surface, but they were satisfied it had no permanency or depth. I am afraid that many who argued thus did so through the necessity of an expedient to explain their failure. Move toward any point of the compass from Mexican gulch, upon hillside or in the ravines, and you find the color of gold. Its small flakes are mixed with every grain of sand, and again it is found imbedded in the eternal rocks. One might imagine from the numberless croppings of rich ledges that Nature's central laboratory for the manufacture of fine gold was located here. But our mining novices had now given up the hunt for gold. After braving a mountain tempest of rain and hail for four days and nights, breakfasting on bread, bacon and coffee, dining on coffee, bacon and bread, and suppering on coffee, bread and bacon, they were hunting for something else. They were looking for an excuse to get back to comfortable homes. They found it in the fact that there was but little gold on the surface, and I think would have been seriously disappointed had anything occurred to make this excuse for their speedy return unavailable. As to the placer mining, it is at best a precarious method of obtaining the means of existence. The miner who picks up a fine nugget one day may be starved out before he finds the next one. Men who are well constituted to stand the severe strain upon their physical system may make a living down there for awhile, but the water will soon be gone and miners must either resort to carrying the dirt a great distance or use dry-washers. Two months from now there will probably be little placer mining done, but it will be resumed with the first rains next winter.

THE ALAMO PLACERS.—Cor. *San Diegan*, March 28: The rush for the new placers on the Alamo has diverted all new-comers, who now visit that vicinity first. Much hard work has been done there already, and gulches supposed to be worthless have been found to yield their treasures of coarse gold. The gold does not seem to run in nuggets so much as in Arroyo placer, but it is rather of a large, mealy character. Rockers are mainly used and the noise of the 300 and odd machines rattling away sounds like a gristmill. So rich is that district that hordes of Mexicans are crowding and jostling each other around the ledges in the vicinity of the springs, a mile above Tyzack's camp, and the dirt and small rock yield good results. Many are making good pay by taking rich pieces of float and pounding out the gold in a mortar, or selling the finest pieces for jewelry or cabinet specimens. Much rock from newly discovered leads is brought in, frequently showing more gold than quartz on the surface. It is peculiar that no quantity of silver ore has yet been found in this district, but fine specimens are shown from San Pablo, 20 miles south. Only one mine, the Visnagre, has been sunk to any depth, and, therefore, it is next to impossible to say whether the ledges go down or not.

MONTANA.

COPPER AT BUTTE.—*Miner*, March 30: "What is the latest news in copper?" is the question uppermost on every one's tongue now. The question is how low will it go? This question was put yesterday by a reporter to a gentleman of long experience in mining matters in the West. "How low will it go?" Well, we on the outside can hardly be asked to give a definite answer to such a question. But you can bet that it won't be allowed to drop to any ruinous figure. Why? Because Haggin, Lewisohn and other producers here will take care that it does not. There was only one course for them to come to to save themselves. They know to a pound what the real surplus on hand is. It is somewhere about 120,000 tons. They know they have to take care of this surplus. It is in the hands of the financial firms who advanced money to the syndicate on it. It has been hypothecated to them. The society of metals, otherwise the syndicate, has served the purpose of its projectors and has come to an end. The surplus is there. Haggin and the large copper producers of this country have only one course. They must take care of this surplus. That is what they have gone to Europe for. When they get there they will arrange to take this out of the hands of the people now holding it. They will, in fact, substitute themselves for the syndicate. The surplus will not be allowed to flood the market. Of course, this will entail a curtailment of production at present and the surplus will be gradually worked off. The mines of Butte can stand a reduction of price better than any other in the world, owing to the perfection of their processes here and the amount of silver in the ore. There will be no diminution in the production here. The accident at the Anaconda necessarily limits work at their mines until the burned smelter is rebuilt. But the camp will continue as prosperous as ever. Copper is not the only product here, you must remember. Look at the amount of leases going on here and the development of new mines in the neighborhood.

THE CHAMPION.—*New Northwest*, March 29: The crosscut was pushed 12 feet into ore without reaching the hanging-wall. On Saturday work was suspended on the head of the crosscut. The station, cut out ten feet high, and the crosscut, about 20 feet, had not been timbered. Rock began dropping behind the workmen, and it was deemed best to return and timber. This is now being done, the crosscut being carried through seven feet high, and timbered as they go. Supt. Ed Mills says the entire lead matter so far is mineralized and milling ore, and he expects to find rich ore on the hanging-wall.

THE HIDDEN HAND.—This is the most developed of the group of the galena silver ledges that have been discovered and worked a few miles east of Deer Lodge since last fall. It is owned by Devan, Peterson & Harries. They are now in 70 feet on the vein, which is three feet wide and has begun to pitch from nearly horizontal toward the vertical. They are taking out considerable ore, which it is believed will run $100 to $170 per ton in silver and lead.

NEW MEXICO.

DEVELOPMENT WORK.—Silver City *Enterprise*, March 29: A steam hoist will be erected on the Ruby Silver at Gold hill soon. Atwood, Baker and Campbell have located and are working an extension of the Rose mine. Dorns and Snyder, who recently located the Silver Giant at Bullard's peak, are taking out some very rich ore. One ton of ore was shipped from No. 2 of the Ben Hobson group at Bullard's peak, by H. H. Betts, which netted $343.70. The shipment of iron ore was resumed on Tuesday. There are now about 3000 tons of ore ready to be moved from the mine and depot. Eight tons of ore from the Reservation mine at Gold hill was recently worked at the Standard mill, returning $300 net in gold. Walton, Polloxfen and Mitchell have secured a 12-months' working bond on the Telegraph mines and mill and will shortly resume operations there. Wm. B. Farish was hard at work for several days this week sampling the Maud S. mine in the Mogollons. A cash offer of $40,000 was made for the Golden Giant at Pinos Altos this week and refused. D. C. Casey, who has a lease on the Silver King mine, at Bullard's peak, has made a strike of nauve silver ore.

OREGON.

BAKER COUNTY MINES. — Bedrock *Democrat*, March 27: During the past few days a large number of mine-owners from the various districts throughout Baker county have congregated in the city, and they make a very favorable report of the past winter's development work on quartz claims. Throughout the sections of Cracker creek, Sumpter, Granite and Cable cove, a greater amount of development work was done the past winter than ever before in the same length of time, and the result has been that some of the best mines of the Northwest have been opened up. With the building of a $100,000 milling-plant on the Eureka and Excelsior mines on Cracker creek at an early day, which is a positive fact, a new impetus will be given the mines of this county. Altogether the mining outlook of Baker county was never better and a more perfect assurance of prosperity was never manifest.

RICH STRIKE.—From parties down from Robinsonville, the reporter learns that a wonderful rich strike of gold ore was made the other day in the Phœnix mine, situated about one mile from Robinsonville. The ore is estimated to be worth from $5000 to $7000 per ton—so rich that the gold stands out in lumps on every piece of rock picked up. The owners of the Phœnix are Cal. Berry, Dave Shote, Chas. Collier and Lem Barnett, a quartet of old miners and prospectors who have mined in the vicinity of their present find for many years.

UTAH.

THE NEW SULPHUR FIND.—Salt Lake *Tribune*, March 29: Hank Barnes returned yesterday afternoon from his new sulphur find west of Frisco, Utah. He brought with him about a third of a ton of samples of the different grades of sulphur found in the deposit, and these range from about three-quarters up to some ninety-eight per cent pure. They are decidedly rich-looking, and if the discovery does not border on the upper crust of Tophet it is decidedly upper crust on its own merits. There is a deposit of this material of unknown vastness, but enough is in sight to promise great things.

THE TRIPOLI DEPOSITS.—The tripoli business is beginning to assume considerable proportions here. There are large deposits of this valuable material near the city, and it only needs to be put through a process of screening to prepare it for the market. One company was incorporated some time ago, and another has now appeared in the field. Their claim is located near the head of Red Butte canyon, and they intend to operate quite extensively this summer. A large quantity of the article has already been prepared and distributed in this city for trial, and jewelers and others who have used it say that it is superior to the imported.

WASHINGTON TERRITORY.

THE DISTRICTS.—Ellensburg *Capital*, March 27: In Peshasten district the miners have been doing considerable work during the past winter, and the output of gold ore has been quite encouraging. The arastra is now busily engaged in crushing ore, and the indications point to a busy season and large product. Peshasten is one of the best free-gold as well as concentrating districts in the Northwest, and with additional capital and development, would make a rich record. In the Swauk placer mines there is considerable activity displayed by the old miners and those who have recently purchased interests. There is water enough for present use, and with proper storage the supply could be made available until later in the season. The gold output this year from the Swauk will be above the average. In the Cle-Elum districts preparations continue for a livelier season than has been known there since the discovery of the first mines. The gold, silver, copper and iron mines are all in process of development. From the Conconully mines reports of extensive strikes and new finds are of daily occurrence. The development work of the past winter has helped these mines materially, and has been the means of creating confidence and causing a number of sales at good prices. Ore from the Conconully will be seeking a market this year, and the output will be something worth considering.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific States.

From the official report of U. S. Patents in DEWEY & CO.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING MARCH 26, 1889.

400,157.—ROCK-CRUSHER—Geo. E. Ames, S. F.
400,034.—CABLE-TUBE PROTECTOR — H. F. Ascheck, S. F.
400,201.—SEPARATOR—Finch & Cross, S. F.
400,401. — PISTON WATER-METER — Frederick Gutzkow, S. F.
400,216.—CONCENTRATOR—J. A. Johnson, S. F.
400,220.—HARROW AND CULTIVATOR — S. W. Kilpatrick, Gilroy, Cal.
400,114.—AMALGAMATOR—N. L. Raber, Corvallis, Ogn.
400,372. — LAMP-SHADE PROTECTOR — G. A. Tank, S. F.
400,155.—WELL-CRIB—W. H. Williscraft, Juniper, A. T.
400,083.—FENCING—E. Hawes, Sacramento, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ROCK CRUSHER.—Geo. E. Ames, S. F. No. 400,157. Dated March 26, 1889. This is one of that class of rock-breakers in which a movable or vibrating jaw operates against an opposing fixed jaw, the rock being crushed between the two. The object of the invention is to increase the capacity and strength of the machine, to reduce its weight and provide simple and reliable means for effecting the several adjustments.

CONCENTRATOR.—Joseph A. Johnson, S. F. No. 400,216. Dated March 26, 1889. This is a machine for concentrating ores, in which both a coarse and fine pulp appear. It consists of a longitudinally vibrating iron table, the surface of which is divided into narrow channels from end to end, each channel having a series of depressions or basins, and, in combination with this, of a series of reciprocating rakes or scrapers, which act to carry the heavy material toward the upper end where it is discharged.

PISTON WATER METER.—F. Gutzkow, S. F. No. 400,401. Dated March 26, 1889. This is one of that class of meters known as piston-meters, and the object is to construct a cheap and accurate meter, the employment of hydraulic pressure exclusively for the actuation of its parts and reversing the stroke by means of a peculiar mechanism. The whole operation of reversing the movements of the valves and of the piston within the meter is effected by the pressure of the water, and the independent movements of the valves prevent any stoppages or dead points. The piston is cushioned at each end of the stroke either by imprisoning a small quantity of water between the piston and the end of the cylinder as the piston covers the ingress point or by means of a projection which enters a corresponding recess in the end of the cylinder.

TUBE OR TUNNEL PROTECTOR FOR CABLE ROADS.—Henry F. Ascheck, S. F. No. 400,034. Dated March 26, 1889. This invention consists in a plate pivoted or hinged within the tube of a cable road and to one side thereof, said plate traversing or crossing the vertical plane of the grip-slot and resting against the other side of the tube, whereby, when at rest, it covers the top or neck of the tube, but is adapted to be moved by the passing grip without interfering with its travel. The invention further consists in the construction and arrangement of a continuous series of said plates, their connection and limiting devices. The object is to protect the tube from snow, dust, dirt, sand and other debris which usually finds its way through the open grip-slot into the tube.

SEPARATOR.—John M. Finch, Crockett, Contra Costa Co., and John R. Cross, S. F. No. 400,201. Dated March 26, 1889. This invention relates to that class of machines for separating materials according to their specific gravity by the application of a current of air; and it consists essentially in a shell or casing having within it a rotating cylinder freely operating, whereby a rotary current or body of air is created, and accompanies the same, an inlet for the feed of the material arranged to deliver it within the sphere of the rotary current or body of air, and independent outlets for the separated materials. In this machine, there being no accession of air, there is no discharge of air. The air within the shell is therefore utilized constantly, and there being no fresh air admitted, the air which is within is needed to make up the full rotary current, none being discharged and the materials thus separated, each portion passes off without any accompanying air, and consequently without dust. The air within is constantly clearing itself of the material and can be used over and over again.

MECHANICAL PROGRESS.

WROUGHT-IRON PIPE MANUFACTURE.—There are 24 wrought-iron pipe works in the United States—one in Massachusetts, two in New York, fourteen in Pennsylvania (of which six are in Pittsburg), one in Delaware, one in West Virginia, two in Ohio and three in Illinois. Owing to the depression which has existed in this trade so long, quite a number of the works throughout the country are idle, but we believe that all that are located here are in operation, and have lately secured a good deal of work, so that they are now fairly busy and prices have been advanced two or three times during the last few weeks. The growth of this industry has been remarkable during recent years, and it now consumes a very respectable proportion of the iron produced. This kind of pipe is now used for purposes not dreamed of a year ago, and the promise is that it will occupy a still wider field. Originally made for conveying water, steam, gas, oil, etc., it is now also used in the construction of cars, for railing, fencing—in short, for purposes "too tedious to mention." The business of making wrought-iron pipe was very profitable, but so many works have been erected during the last few years that margins are extremely small; indeed, during the past summer manufacturers said that some kinds of sizes of pipe were sold at a positive loss. The discovery and utilization of natural gas gave a tremendous impetus to the industry, and was also the chief cause of the erection of several new works and the consequent over-production, but for several months past there has not been so much demand from the natural gas companies, and this has been, perhaps, the chief cause of the severe depression.

IRON AND STEEL IN SHIP-BUILDING.—The English correspondent of the *American Manufacturer* says that the controversy which is indicated in this heading is not after all ancient history to the degree that some persons would imagine. The comparative ease with which steel corrodes together, with its costliness, has lately exercised considerable influence in the temporarily re-establishing iron in favor in some quarters as a ship building material. The committee of officials at Lloyd's Registry have found it advisable to modify their rules upon the matter because of recent developments. They accordingly issued for 1889 a series of new rules for steel vessels, amended rules for iron vessels, which, "striking a balance," may be said to favor iron considerably more than the Registry's previous regulations have done. Of course, anything that lessens the difference between the thickness of iron and steel plates—as the rules do—must, while the prices of the two materials are so far apart, contribute considerably to the increased adoption of iron. Therefore, iron manufacturers are just now deriving a good deal of encouragement from the rules to which I have referred. How long the favor re-accorded to iron will last, is, however, in view of continued steel progress, a very doubtful matter.

IRON RAILWAY TIES NOT A SUCCESS.—The Pittsburg *Dispatch* states that the Pennsylvania Railroad Company has given up the experiment of substituting iron railway crossties for the wooden ties now in use. The iron ones in use on the middle division and in the Philadelphia yards will be taken up and will probably be sent back to England, whence they came. The iron ties have been in use almost a year, but owing to their not having the elasticity necessary for the "giving" of the rails, they have not proven a success. Another reason to prevent their general use is the cost. As long as wooden ties can be purchased at about one-third the cost of iron ties, the former will continue to be used. An iron tie cannot be made to weigh much less than the present wooden tie, or about 250 pounds. The life of a wooden tie is from 9 to 12 years. Where the ground is well drained, some of the best white oak ties will last longer than that time. They cost about 50 cents each, and are made at nearly every sawmill in the country. It is estimated that, when put down, packed, lined, etc., they will cost about $1.10 each. This includes labor and everything. A second-class tie will cost about 44 cents delivered on board the purchasers' cars.

DESTROYING MACHINERY.—It is a fact that more machinery is destroyed through ignorance and carelessness than by use. Men who are very careful, and even miserly, in their money matters are often the ones who lose most by bad management and carelessness in regard to the use of their machinery. Indeed, in many cases the premature breaking down of well-made machinery is directly traceable to the miserly instincts of the owner, and his unwillingness to employ and pay a competent person to care for and operate it. Of all penny-wise and pound-foolish policies, this kind is the least excusable. It often brings undeserved blame and discredit upon the honest manufacturer, which is not compensated by the additional profit he may derive from replacing the worn-out machines with new ones.—*Southern Lumberman.*

COMPOUND ARMOR VS. STEEL PLATES.—The long-continued experiments which have been conducted on board the Nettle, at Portsmouth, with the view of determining the respective merits of compound armor and of solid steel armor as a protection for battleships, have just been brought to a close. Only two Sheffield manufacturers sent in compound samples for competition, but the number of steel plates forwarded for trial amounted to eight, from as many makers, being two less than were expected. The ten-inch plates were attacked by steel and Palliser projectiles, at a range of 30 feet, and although two of the solid steel armor plates at least underwent the crucial ordeal with satisfactory results, the superiority remained with the steel-faced armor now adopted in the navy.

STEEL SPIKES.—A New Castle (Pa.) dispatch says that a series of experiments were tried at the Etna Iron Works on January 7th, in the manufacture of steel railroad spikes. The object is to make a finished article by rolling the bar so that its width will be the length of a spike, and in such a shape that the spikes may be cut from it with shears, pretty much as a cut nail is made, except that the head is formed in the rolling process. The first test was made by running through some steel rails that had been slowly heated for 2½ hours. The result was fairly successful, and it is thought that a few changes in the rolls will make the operation entirely satisfactory. Should the scheme be successful, it will work a revolution in the cost and manner of making railroad spikes.

AMERICAN STOVES IN EUROPE.—American stoves are so far superior to those in common use in large parts of Europe that manufacturers here might reasonably expect to find markets abroad sufficiently ample to absorb all their possible surplus. But a difficulty exists in the inferior coal consumed on the continent. Not long ago a Pittsburg manufacturer shipped a lot of stoves to Germany, and, being informed that they failed to give satisfaction, learned after investigation that the coal used produced many clinkers and slag. The better grades of coal were too expensive for general consumption. A variety of artificial substitutes can be had, but as a rule economy is consulted rather than comfort.

STEEL CARS are fast coming into use. A large manufactory of such cars will soon be put in operation for their manufacture in Chicago under a California patent. The first steel postal car ever constructed has just been finished at the railway shops at New Albany by the American Fire-Proof Steel Car Company. It is built of plates of steel, lined with asbestos, and is admirably braced by means of steel rods running the entire length of the car, the rods being fastened by an ingenious device into the steel posts. The floors are of steel, as are the platforms and steps, and there is no wood whatever about the car except the timbers of the trucks.

HOW TO DRILL HARD STEEL.—Having to put a pivot in a pinion-wheel, on attempting to drill, I found no drill that I could make would cut it. I thought of trying the same lubricator as for cutting or drilling glass, viz., turpentine, and to my great surprise I found the same drills cut freely and enabled me to get over the difficulty. In a long experience and with many men, I never heard of it being used before, and if not generally known, if tried I am sure will remove a difficulty that I know has existed with many repairers.—*Manufacturing Jeweler.*

CALIFORNIA IRON.—The Pine-Street Railway Company of this city has earned the gratitude of the iron manufacturers of the State by promising to use California iron in the construction of the new cable railway on Pine street. California-made wheels are in use upon the Geary-street road, and are found to be just as good as the Eastern article. A committee of the iron trade has or will wait upon the Directors of the Hibernia Bank and request them to specify in all contracts for iron work that it must be made in this State.

LOCOMOTIVE-BUILDING IN RUSSIA.—According to a correspondent of *Industries*, the Russian Minister of Railways proposes asking for a credit of 9,300,000 roubles for the purchase of 300 locomotives. Each engine, according to these figures, will cost over $23,000. The engines are all to be built in Russia.

HOLLOW STEEL INGOTS are being made in Sweden by casting steel in molds hung on trunnions, allowing the sides to chill to the required thickness and pouring out the steel still liquid in the center. These hollow ingots go to England, where they are drawn out cold to tubing.

TO WHITEN BRASS.—Small articles of brass or copper may be whitened by boiling them in a solution of three-fourths of one pound cream of tartar, two quarts of water, and one pound of grain tin or any pure tin finely divided. The tin dissolves in the cream of tartar and is again precipitated on the brass or copper.

DR. WILLIAM GARRARD, the first manufacturer of tool steel in the United States, died of old age at his home in Fallston, Pa., on Monday, March 18th, aged 86 years. He first engaged in the steel business at Cincinnati, Ohio, in 1840.

DRILL POINTS heated to a cherry-red and tempered by being driven into a bar of lead, will bore through the hardest steel or plate glass without perceptibly blunting.

SCIENTIFIC PROGRESS.

Recent Changes at Niagara Falls.

There have been recently two very heavy falls of rock at Niagara Falls. At first a mass of rock fell from the Horseshoe falls, and 24 hours later another mass was precipitated into the abyss below, with a noise so closely resembling that of an earthquake as to alarm the residents of the neighborhood. The result of the displacement is a change in the shape of the fall. Formerly the Canadian portion of the fall could be described as a horseshoe; but the breaking away of rocks in the center some years ago made it V-shaped. Now that a further displacement has occurred, the fall has returned to its old condition. It is, of course, generally known that the Falls of Niagara are gradually moving to the south. The deep cut through the solid rock marks the course they have taken in their backward movement. It is a wonderful excavation, a chasm dug out by the sheer force of water. Not less astonishing has been the removal of the debris. The rock has been thoroughly pulverized, and has been swept out of the river to be distributed in Lake Ontario. Once it was thought that in the wearing-away process the falls would reach Lake Erie, and there degenerate into a series of rapids. But the theory has been set aside by one which retains the cataract, although the latter will be the shadow of its present self, and much reduced in size. The latest idea is that the falls will recede two miles and then remain stationary, their hight at that point being 80 feet, instead of 164, as at present. The supposition is supported by an argument which appears reasonable. The present site is a limestone formation, some 80 or 90 feet thick, with a shaly foundation. As the shale is washed away the limestone breaks off, and the falls take a step backward. But the end of the shaly deposit will be reached two miles from the present falls, and then the rushing water will have more than it can do to wash away the solid precipice over which it will be projected. It would be a waste of time to attempt to estimate the number of centuries that will elapse before Niagara Falls have found their permanent site.

CHEMICAL ACTION OF A MAGNET.—The chemical action of a magnet has been described by H. A. Rowland and L Bell in the *Journal of the Chemical Society*. Two iron rods are imbedded in insulating material, the point of one and the side of the other being laid bare by removing the insulation. The rods are placed in a beaker between the poles of an electro-magnet, and connected with a galvanometer. They are acted on by various reagents. When perpendicular to the lines of force, no current is produced. When parallel, a current is produced, the sharp-pointed rod forming the negative element; soon afterward reversal takes place. The direction of the current is independent of that in the magnet. Similar but much weaker effects are produced with nickel and cobalt. The action is greatest with substances which, like nitric acid, attack the iron without evolution of hydrogen. The reversal can be annulled by preventing motion in the liquid by means of gelatine or sand. The electro-motive force varies from 0.0001 to 0.02 volt. The evolved hydrogen probably acts mechanically in reducing the current. The protection of the pointed end from the reagents is due to the increased energy required to remove the iron in opposition to magnetic attraction. No differential action is observed with plane surfaces, but where a point occurs, protection ensues, and the elevation increases in size.

CLOUD MEASUREMENTS.—Some very important work in the measurement of clouds is now performed at the University of Upsala, Sweden, which has attracted much attention among meteorologists. When opportunity offers, the hight of clouds is determined thrice by simultaneous observations at two telephonically connected stations about a mile apart; the angles of conspicuous points are carefully noted by means of specially adapted instruments, thus affording data of a much more satisfactory character for fixing distances than have been obtained by the photographic method. Clouds have in this way been measured at the great hight of nearly 44,000 feet, and the immense velocity of 112 miles an hour has been ascertained in the case of a cloud 28,000 feet high. One of the most interesting results which has been developed by these measurements is the fact that clouds are quite regularly distributed in three layers, the mean summer levels at this point of observation showing the suggestive data: Low clouds—stratus, cumulus, cumulonimbas, 2000 to 6000 feet; middle clouds—stratus cirrus, 12,000 to 15,000 feet; high clouds—cirrus, cirro-stratus, cirro cumulus, 20,000 to 27,000 feet.

A NEW PRINCIPLE FOR KEEPING PLANTS through the winter without artificial heat was recently shown at Regent's Park, London, with the plants grown in them last winter. The essence of the invention is that all light and heat shall previously pass through a shallow layer of water. The water is found to exercise great control over temperature, protecting plants entirely from frost in winter and from excessive direct heat in summer. The application involves no difficulty. In the case of a garden frame, a sliding "water-light," about three inches deep, is made to fit over the frame containing the plants; the only difference from a glass light being that it holds water and is always placed in a flat position. The depth of water generally kept in the tank is about two inches in winter and summer, and half the depth in spring and autumn.

LIFE MAY CANNOT SEE.—Not only are the ultimate divisions of matter vastly beyond man's powers of assisted vision, but even living animals are known of such smallness that the most powerful microscopes fail to reveal them. According to Dr. Royston Pigott, the bacilli (rod-shaped bacteria) of typhoid fever are filaments only 1-500 of an inch long and 1-125,000 of an inch thick. Such germs are gigantic, however, in comparison with some of the micrococci (spherical bacteria) seen in putrid meat infusions. These are usually from 1-25,000 to 1-30,000 of an inch in thickness, and are sometimes inconceivably more minute. The smallest of the micrococci are discoverable in decomposing cod's head, the organisms on bursting from their parental sac being utterly too small to be recognized by any instrument. It is estimated that at birth they must measure considerably less than one-millionth of an inch, and they can only be discovered after some hours of growth. Yet when first visible their forms comprehend the special apparatus of their fuller organized life.

CURIOUS ILLUSION.—A curious illusion of vision has been made the subject of investigation by a French scientist, the result of which, it is thought, may account for the apparent oscillations or swinging of stars sometimes observed; that is, on the eye looking constantly, for a considerable period of time, at a small, feebly lighted body, itself being in complete darkness, the body appears to oscillate or to describe certain curves. A study of this phenomenon has led to the conclusion that it is of the subjective order, appearing to be, in fact, of the same nature as the movement of a star observed when a person leans his hand against a wall and fixes his eye upon the star, the star appearing to be agitated in its place and to oscillate rapidly. In order that the motion be noticed, there should be no moon and the sky should be clear.

SIZE AND MOVEMENTS OF TORNADOES.—Prof. J. P. Finley gives the width of the path of destruction in tornadoes, as determined from the records of 88 years, at from 10 to 10,560 feet, the average being 1369 feet. The length of the tornado track varies from 300 yards to about 200 miles, the average being 24.79 miles. The velocity of progression of the tornado cloud varies from 7 to 100 miles an hour, the average being 44 11 miles. These extremes may often occur in different portions of the track of a single tornado. The shortest time occupied by the tornado-cloud in passing a given point varies from "an instant" to about 20 minutes, the average being 74 seconds.

LIFE OF INSECTS.—It is well known that Sir John Lubbock has shown how long insects may live when kept out of harm's way. The greatest age yet attained by any insect, so far as is known, is that reached by a queen ant (*Formica fusca*), which lived in his care until August 8, 1888, when she must have been nearly 15 years old. Another queen of the same species died at the advanced age of over 13 years. He has now a queen of another kind of ant (*Lasius niger*), which is more than nine years old "and still lays fertile eggs, which produce female ants."

WHY FIRES BURN BRIGHTLY IN WINTER.—There are several reasons why a fire burns so brightly in frosty weather. First, the air being cold is denser, and the heated air and gases from the fire are comparatively more buoyant, consequently there is a greater draught. Then the air, being denser, contains more oxygen in an equal volume, and that gas being quickly supplied, the combustion is fiercer and more perfect. In frosty weather, too, the atmosphere is comparatively free from moisture, which of course has a tendency to intensify a fire.

LOST COMETS.—According to Prof. Kirkwood's researches, 7 of the 20 known comets of short period have disappeared, either by breaking into fragments or by the transformation of the orbit by the influence of Jupiter. He has heretofore given reasons for concluding that two of the short period comets were asteroids drawn from their orbits by Jupiter's attraction, and he now advances evidence tending to show that the entire 20 were originally small planets.

THE AURORA BOREALIS.—Before the Royal Society, London, Norman Lockyer recently read a paper on the spectra of the aurora borealis and of the lightning flash. He attributes the aurora borealis to minute particles of dust floating in the highest regions of the atmosphere, which dust he supposes to be produced by the fall of meteors.

THE AMERICAN ASSOCIATION for the Advancement of Science is to meet at Toronto, Can., Aug. 27th, and the expectation is that the occasion will attract a large number of visitors. The session will probably close on the 4th of September.

A CULTIVATED DANDELION.—It is said that a florist at Lancaster, Pa., has so improved the dandelion that he has produced specimens ten inches in diameter.

Good Health.

Paralysis Becoming More and More Common.—There is a disease which is certainly becoming more common every day, writes Dr. W. A. Hammond to the Pittsburg *Dispatch*, and from which recovery is so rare that many physicians most capable of judging doubt if it ever takes place, and that is general paralysis, or general paresis, as it is sometimes called. While probably not resulting from any particular occupation, as such, it may be caused by any employment which is above the mental capacity of the individual, or which involves great anxiety or in which there are reverses or disappointment. It is especially prevalent among those who are engaged in financial speculations or in some business requiring inventive powers or a degree of knowledge which the person does not possess. It is a most terrible outcome of the struggle for wealth and position in which the whole civilized world seems to be now engaged. Those who are satisfied with their lot in life or who, if not contented, have no hope of improving their condition, and hence make no effort in that direction, are never affected with this disease. I doubt if a single case occurred among the slaves of the South, while since their freedom it has made its appearance among them and their descendants. There are both mental and physical symptoms in general paralysis, and while the approach of the disease is generally insidious, its presence is indicated by certain phenomena which are unmistakable in their significance. Chief among these is what the French call *delire de grandeur*, the delirium of grandeur. The patient, for instance, imagines that he is the richest or the most powerful, or the strongest or the handsomest man in all the world.

Emotional Prodigality.—Something has been wisely said of late about the danger of over-pressure in our schools. The time spent in study that ought to be spent in outdoor play or in exercise in gymnasia is worse than wasted. But the over pressure of intellectual work would not be so bad were it not for the emotional prodigality of many children both at home and at school. Teachers are spurred to strain pupils to the utmost that they may meet the coming tests for promotion. The healthy, spontaneous emotions that make it the delight of childhood to learn are crushed, and factitious emotions of fear and dread are substituted. At home the emotional excitement is often greater than at school. Prizes, the expectations of parents, piano practice, company, parties, dances, petting and reproofs are the stimuli, culminating often in late hours spent in preparing a half-dozen lessons for the next day. The tasks at school, hard as they are, often are less injurious to children than the emotional dissipation at home. Again, the storm and stress of emotional activity that often occurs at adolescence is liable to cause an alarming waste of energy; and there is danger that habits will then be formed of allowing the emotions to evaporate or to expend themselves in unessential, pedantic and morbid activities. Whoever revels in emotion and squanders nervous energy at one period of life will lack the needed support for intellectual activity at another period.—*From "Economy in Intellectual Work" in Scribner's Magazine.*

Climate and Distribution of Cancer.—In concluding a series of papers on the geographical distribution of cancerous diseases in the British Isles, A. H. Haviland says (*Lancet*, March 10, 1888): "I maintain that those who would give themselves the best chance of avoiding those local conditions which are coincident with a high death-rate from cancer should study well the distribution of this disease in England. There is abundant evidence there to show that cancer does not thrive in high, dry localities, where the soil is kept sweet by the absence of floods, and the nature of the rocks which either underlie it or form its principal constituents; and that it does thrive and become very fatal where floods prevail, where their emanations are sheltered and intensified, where vegetation is killed and decomposed, and where, after the floods have passed away, a rank herbage springs up, composed of sour grass and bitter plants, which scour and otherwise disease the horses, cattle and sheep that feed upon them. Much has to be done, much has been pointed out, and if the 22 high mortality and the 16 low mortality districts were well studied in connection with the various factors which we have seen to be coincident with high or low death-rates, I believe that much would be added, much would be corrected, and much revealed that we little think of now."

The Axe Cure for Colds.—"I can tell a cold the moment it gets a grip on me," said an old farmer of my acquaintance, "and I have cured them lots of times without spending a cent for medicine. The minute I feel it coming, I hunt up my axe and start for the woods. The toughest old stump I can come across will suit me best, and if I can manage to work myself in a sweat I know I'm as well as cured. A few minutes after, the thing begins to loosen on my lungs, and then I can cough it out in short order." Arm-exercise would, indeed, seem to act as the promptest specific in such cases, and dumb-bell practice misses its purpose more frequently only on account of the circumstance that muscular efforts with practical purpose can be kept up much longer than crank-work gymnastics. Swinging a heavy axe is really much harder work than Indian club exercise, but the visible results of the effort, the flying chips and widening splits, appear to act as a mental stimulus in preventing fatigue.—*American Rural Home.*

The Best Mode of Preparing Beef Tea for the Sick.—Take one pound of lean beef cut into small pieces. Put into a jar without a drop of water; cover tightly, and set in a pot of cold water. Heat gradually to a boil and continue this steadily for three or four hours, until the meat is like white rags and the juice all drawn out. Season with salt to taste, and when cold, skim. The patient will often prefer this ice cold to hot.

Comparative Fatality of Drinking Men. In all the Prussian hospitals during the year 1878-79, there died from the ranks of the drinkers 19 per cent, while from the entire number of patients there was only a mortality of 10 per cent. Of those afflicted with pneumonia, 53 per cent of the drinkers died, while only 18 per cent of the other pneumonia patients died.

Suicides.—It is said that Saxony furnishes the largest percentage of suicides of any civilized State. The number last year was 1104, or one to about every 3000 of the population. In 1881 the total number was 1248.

A New Remedy for Mumps.—It is said that the Lewiston (Me.) druggists keep large quantities of tow for sale. It is in great demand as a remedy for mumps. It is worn around the neck of the patient.

To Avoid Consumption.—Will Carleton attributes his escape from early death by consumption to daily and persistent inflation of the lungs with fresh air. He is now 42 years old.

No Alcoholic Stimulants.—The homeopathic hospital in Philadelphia was successful in restoring patients from typhoid fever last year without the use of alcoholic stimulants.

The Morphine Craze is growing. A Portland, Me., manufacturer has made and sold 25,000 hypodermic needles since 1886.

Useful Information.

How to Save Sagging Plastering.—The ceiling must be first pressed back into place. To do this, take two pieces of scantling, long enough to reach over the defective part. Nail upon them laths about two or three inches apart. Place this framework, lath side up, against the plastering above them. With other pieces of scantling, reaching from this framework to the floor, support and lift it up against the ceiling, driving wedges under the floor end of the supporting scantling, which will bring the ceiling in place and keep it there. To prepare the nails: Put them in a vise. With a hack-saw, saw slots in their heads like a screw (only slightly, but so that a sharp screwdriver will hold in the groove), then with the screwdriver turn the nail to the right and then to the left, gently pushing it first through the plastering, then into the lath above, still pushing and gently turning. The head of the nail can be screwed into the plaster flush, so as to make a neat job, and hardly be noticeable on the floor beneath. The nails hold very firmly. Once in every six, eight or ten inches square for a nail will be usually sufficient. If the plaster is very porous and shaky, small copper washers may be used on the nails, but it must be very far gone to need them. Driving nails in with a hammer would destroy the whole fabric. Take down your lath framework, and there you have your piece of ceiling as firm and nice as it ever was.—*Scientific American.*

The Wood-Oil Industry of Sweden seems to be rapidly growing into considerable importance. The French scientific journal *La Nature* states that the extraction of oil from wood in Sweden is becoming year by year a more important industry. Those parts of the trees which have hitherto been regarded as useless, such as the stumps and roots, are no longer left in the forest to rot, but are subjected to various methods of treatment, by which not only wood oil, but also turpentine, creosote, acid of vinegar, charcoal and tar are obtained from them. The oil as it is now usually extracted cannot be burnt in ordinary lamps, for it smokes too much. But it may be used in special lamps, which are not dissimilar to the usual photogen lamps. The latter can easily be adapted to wood oil, and when the oil is mixed with a certain quantity of photogen it may be consumed in ordinary lamps. It costs about 3d. per pint, it does not explode and lasts 25 times longer than photogen. When intended for lighting it is extracted wholly from pines and firs. Thirty factories in Sweden make its extraction part of their business and the production is now considerable.

The Fist and the Foot.—A youth who went into a Buffalo store and asked for socks, not knowing the proper size, was told to hold out his hand. The customer held out his hand and doubled up his fist as directed. The clerk took a sock from a box, wrapped the foot around the fist and guaranteed a perfect fit. "I am just as sure it will fit you as though I had measured your foot," said he, "as the distance around the fist is always the length of the foot."

How Coffee Came to be Used.—It is somewhat singular to trace the manner in which arose the use of the common beverage of coffee. At the time Columbus discovered America it had never been known or used. It grew only in Arabia and Upper Ethiopia. The discovery of its use is ascribed to the Superior of a monastery in Arabia, who, desirous of preventing the monks from sleeping at their nocturnal service, made them drink the infusion of coffee upon the reports of shepherds, who observed that their flocks were more lively after browsing on the fruit of the plant. Its reputation spread through the adjacent countries, and in 200 years it reached Paris. A single plant, brought here in 1714, became the parent stock of all French coffee plantations in the West Indies. The Dutch introduced it into Java and the East Indies. The extent of the consumption can scarcely be realized. The United States alone annually consume it at the cost, at its landing, of from $15,000,000 to $16,000,000.

Floated by Means of Dead Cattle.—It has been said that every work of invention has its parallel in nature. But it would not be anticipated that the method of raising sunken steamers by forcing air into casks which have been secured to them would find such a parallel. Yet such has been the case on the Ohio river, where the steamer Robert B. Carson sank near Evansville, Ind., drowning 30 head of cattle that were confined on the lower deck. Efforts to pump the vessel out were not successful, and the boat was abandoned. A few days later, however, it was found to be floating, the fact that the putrefying carcasses of the cattle had become inflated by the gases generated in putrefaction, and their combined buoyance was sufficient to raise the steamer again.—*Scientific American.*

To Prepare Shellac for Use.—Shellac can be dissolved in alcohol and kept in a liquid form, in a close-stopped bottle, to prevent evaporation. To use it, it is only necessary to apply it where necessary by the pointed end of pegwood, or small camel's-hair brush, and gently heat over a lamp, when it will quickly solidify; or, it may be used as received from a drug store. A good way to do when setting pallet jewels, ruby pins, etc., is to heat a piece over the lamp and draw it out to a long, slender thread, then break the end in small particles of suitable size for cementing the jewel. By this means the shellac can be placed just where it is needed, and it will not run over the pallets or table roller.

Beet Root Sugar in Nebraska.—Nebraska, it is said, will enter this year upon the manufacture of beet-root sugar on a scale of some magnitude. Those who will engage in the culture are mostly Germans who have been skilled in the raising of the sugar beet in the old country, and a large sum has been subscribed to secure the production of the beet sugar in the market. It is said that the soil is adapted to the cultivation of beets and the climate favorable, but this can be claimed only after the experiment has been fully tried.

Acids in Lubricating Oils may be detected by analysis in a laboratory, or by putting the sample to be tested in a clear glass bottle with copper wire running down through the cork, air-tight. Stand the whole in a sunny place for two or three weeks, and then, on removal, if verdigris or green rust appears on the copper, an acid is in the oil.

The Telephone Investment.—The Bell Telephone Company is looking ahead, and proposes to expend $50,000,000 additional before the expiration of its patent and contract with the Western Union in 1893. After that time the company will have the finest telephone and telegraph system in the world.

Reducing Working Hours.—Edward Atkinson says that in the last 50 years factory work has been reduced from twelve or more to ten hours per day; in the building trades from eleven or twelve to nine or ten hours.

Onyx.—The Mexican marble, which we know as Mexican onyx, is not onyx at all. Onyx is an agate consisting of parallel layers of chalcedony. Marble is a carbonate of lime.

Lignum-Vitæ has been successfully used for blocks on piston cross-heads, and is said to be superior to metal for that purpose, requiring less oil and never heating.

An Alloy.—Compounded in ten parts aluminum and ninety parts copper, that simple alloy gives the best bell metal and the finest gun metal in the world.

A Muscular Potentate.—The Czar of Russia recently picked up 700 pounds of steel in a Petershoff gun factory. The workers cheered heartily.

Paint Stains that are dry and old may be removed from cotton or woolen goods with chloroform. First cover the spot with olive oil or butter.

Pump and Piston.—The ordinary speed to run a pump is 100 feet of piston per minute.

Forest Commissioner Miller.

Referring to the Governor's appointment of Joaquin Miller as a member of the State Board of Forestry, the *Alta* says:

It is excellent in all its bearings. The new Commissioner is a man of world-wide fame, and this linking of his name with California is to the State's credit. But aside from this, he has a profound knowledge of forestry. It is that kind of knowledge which can be gained only by the most affectionate and appreciate conversation with Nature. His lore was learned in the forests primeval, and its lessons have been sharpened by travel and observation in many lands where civilization and the forests have declined and decayed together. The late Gov. Bartlett, appreciating his merits, appointed him to represent the State at the last National Forestry Congress, and his paper read to that body was not only a most delightful literary performance, but a keen, practical discussion of the subject. It has been translated and published in Europe, where its conclusions are accepted by individuals and official bodies specially interested in the preservation of forests. In his own original way Joaquin Miller will convert the functions of the Commission to practical uses immensely beneficial to the State. In his lofty homestead in the Contra Costa mountains he has, with his own hands, toilfully assembled the useful and ornamental members of a forest family of trees, whose umbrage will, in after days, be made classic by his memory. His work with spade and pick has already written on the far-rising slopes a poem in trees, which will be read by thousands who look upon it from the bay in the future years, when what he has wrought there will be among the places of refined pilgrimage which add to the attractions of San Francisco.

Timber on Government Land.—A rule of the Department made on the 28th day of April, 1888, by the Commissioner of the General Land Office, and approved May 12, 1888, by the Secretary of the Interior and Attorney-General of the United States, and which is now in force, reads as follows: "Homestead or pre-emption claimants who have made bona fide settlements upon public lands, and who are living upon, cultivating and improving the same in accordance with law and the rules and regulations of this Department, with the intention of acquiring title thereof, are permitted to cut and remove, or cause to be cut and removed, from the portion thereof to be cleared for cultivation, so much timber as is actually necessary for that purpose or for buildings, fences and other improvements on the land entered. In clearing for cultivation, should there be a surplus of timber over what is needed for the purposes above specified, the entryman may sell or dispose of such surplus; but it is not allowable to denude the land of its timber for the purpose of sale or speculation before the title has been conveyed to him by patent. The abandonment of a settlement claim after the timber has been removed is presumptive evidence that the claim was made for the primary purpose of obtaining timber."

The Floating Logs and the Ocean Currents.—Mr. Leary, of big raft fame, may console himself for the loss of the great raft that broke up off the New England coast with the knowledge that the logs are not floating in vain. They are still making their way eastward and southward in large numbers, and when sighted by vessels their exact position is noted and a memorandum sent to the Hydrographic office in Washington. Already many of these reports have been received and compared, and the result is a chart, that could not have been obtained in any other way, showing the courses of various ocean currents.

The United States Fish Commission has expended $140,000 during the past year on this coast in constructing hatcheries, collecting eggs for distribution, etc. The superintendent, Livingston Stone, reports that 1,500,000 salmon eggs were taken from the McCloud river hatchery. The greater number of these were hatched and placed in the streams again.

Honduras Mines.—The famous group of silver mines at Opoteca, at present owned by Capt. F. M. Imboden, are about to be worked on a large scale. In the last century the above mines were worked by the Spanish Crown to a large extent, producing for years large amounts of silver. English capital will work these mines.

A whale and her suckling calf were washed up on the beach at Santa Barbara light during the recent storm, and, becoming stranded at low tide, could not get off. The mother whale was 60 feet long and the young one eight.

Gov. Waterman has announced his intention to set aside and appoint Tuesday, April 30th, as a legal holiday, in commemoration of the organization of the Government of the United States under the Constitution.

The Anaconda people believe that the fire which caused the loss of the big reduction works was undoubtedly the work of an incendiary.

Mr. Mitchell, who has been nominated for Commissioner of Patents by the President, is a patent attorney of New Britain, Conn.

TABLE OF CONTENTS.

EDITORIALS.—Wheeler's Improved Surface Condenser; Manganese Ore, 239. Passing Events; Surface of Mining Claims; Astronomical Society of the Pacific; Maritime Protection. 246 Crushing Lumps of Roasted Ore; The Late Arthur Nahl; Ozocerite, 247.

ILLUSTRATIONS.—Wheeler's Surface Condenser, 239. Machines for Grinding Soft Ore, 247.

CORRESPONDENCE.—Raining Rocks, 240.

MISCELLANEOUS.—California River and Harbor Commission; Notes on Leaching Silver Ores; The Sprague Electric Railway, 240. Mossbrae Falls; Clay Selvage, 241. Forest Commissioner Miller, 245

MECHANICAL PROGRESS.—Wrought Iron Pipe Manufacture; Iron and Steel in Ship Building; Iron Railway Ties Not a Success; Destroying Machinery; Compound Armor vs. Steel Plates; Steel Spikes; American Stoves in Europe; How to Drill Hard Steel; California Iron; Locomotive-Building in Russia; To Whiten Brass, 244.

SCIENTIFIC PROGRESS.—Recent Changes at Niagara Falls; Chemical Action of a Magnet; Cloud Measurements; Life Man Cannot See; Curious Illusion; Size and Movements of Tornados; Life of Insects; Why Fires Burn Brightly in Winter; Lost Comets; The Aurora Borealis; A Cultivated Dandelion, 244.

GOOD HEALTH.—Paralysis Becoming More and More Common; Emotional Prodigality; Climate and Distribution of Cancer; The Axe Cure for Colds; The Best Mode of Preparing Beef Tea for the Sick; A New Remedy for Mumps; To Avoid Consumption; No Alcoholic Stimulants, 245.

USEFUL INFORMATION.—How to Save Sagging Plastering; The Fist and the Foot; How Coffee Came to be Used; Floated by Means of Dead Cattle; To Prepare Shellac for Use; Beet-Root Sugar in Nebraska; The Telephone Invesment; Reducing Working Hours; Onyx; An Alloy, 245.

OUR LUMBER INTERESTS.—The Lumber Trade; Timber Lands in Fresno; Origin of our English Lumber Trade; Immense Franchises Involved; Giants of the Forest; The Forests of Washington Territory, 249.

MINING SUMMARY—From the various counties of California, Nevada, Arizona, Colorado, Idaho, Montana, New Mexico, Oregon, Utah, Wyoming, 242-3.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 254.

Passing Events.

The Somerville coal mine at Mt. Diablo has been started up again after lying unworked for the past 13 years. The mines in that region are the most important and productive ever found in this State, though of late years the output has been comparatively limited, better coal now coming from the upper coast.

The news of the terrible hurricane in the South Pacific, during which six men-of-war were wrecked and many lives lost, has been the sensation of the week. The hurricane did great damage in many of the groups of islands, though few details of the losses have yet been received.

Letters have been received from Stanley, the explorer, who has found Emin Pasha, but who has had terrible experiences during his trip through Africa. Vast forests have been traversed during the march, and many hostile tribes met.

Several small local "gold excitements" have been started of late in the southern counties of California. The old Julian and Banner districts, in San Diego county, are again attracting attention, mainly through the richness of Governor Waterman's Stonewall mine at the foot of Cuyamaca mountain, some eight miles from Julian. These mines were discovered in 1869, but of late there has been a revival of interest and many prospectors are hunting the hillsides and mountains in hopes of finding another Stonewall.

Surface Ground of Mining Claims.

Side Lines and Boundaries.

In deciding the suit of the Found Treasure vs. North Commonwealth mines, Tuscarora district, Nev., some important points relating to the side lines of claims, and the powers of the U. S. Land Commissioner, were passed upon. Plaintiff attacks the validity of the patent—for the full quantity of the surface ground granted by it—for the reason that it appears upon the face of the patent that more surface ground was ceded than is allowed by the mining laws of Congress, and contends that this objection is also fully confirmed by the papers introduced by the defendant and the proofs offered to support the patent.

The defendant insists that the patent cannot be attacked collaterally, that the commissioner had full jurisdiction to act, and that his action is conclusive. It is undoubtedly a well-settled principle that in actions at law patents are not assailable collaterally; that the patent is conclusive as to all matters, the commissioner acting within the scope of his authority.

This was not an action at law and the patent was not collaterally impeached; but was directly in issue. On April 19, 1878, Epply made a location of 1120 feet upon a lode extending on the vein northerly and southerly each way 560 feet from the shaft. The notice designates the shaft then being sunk as the point of the ledge and the location of the claim. The following day U. S. Deputy Surveyor Tracy made a survey of the claim, and as he is required to do by law to note all workings, improvements, etc., on the claim surveyed by him, specified in his field notes of the survey, that the only workings upon the ground was a shaft with shaft-house then being sunk, 118 feet deep. A claim cannot be located under the law until a ledge or vein is discovered.

The judge concludes from all the evidence that this deep shaft referred to was the point of discovery. In none of the proceedings is any other shaft referred to at the time of location and survey. The ledge being discovered at this shaft, Epply was entitled to 300 feet of surface, on each side of the ledge, and no more. The law expressly limits the locator to 300 feet from the center of the ledge, and when explorations have not been made to determine the width of the ledge, it is a settled principle that the center of the discovery shaft shall be taken for the purposes of locating this 300 feet of surface. The witness Mr. Banfield testified that the discovery point was in a shaft 12 feet deep, then being sunk near the location point. The plat of the ground, accompanying the application for patent, and the plat in the patent as issued, does not contain any such shaft; the only points designated in these two plats is the deep shaft referred to and the point of location, distant 58 feet from this shaft. If the discovery shaft had been at the place it is now claimed to have been, it would undoubtedly have been so characterized in the plat of the claim for the patent, and as well as in the patent itself. On the 27th of November, 1883, the Commissioner of the Land Department refused to grant the application for a patent, as applied for, for the reason that the shaft as designated in the application, and on the plat accompanying, the shaft mentioned and located was the discovery shaft, and the distance from it to the southerly line was more surface than they were entitled to receive. At this time the plaintiff was in possession of and working the claim, and within the southerly line, possibly, as the defendant claimed this line to be at the trial. Upon receiving this notification, the defendant sent to the land office direct, without filing in the land office at Eureka, affidavit that the discovery was at or near the location point. The commissioner thereupon caused the patent to issue. The vein in contention is not the one located, but a side one that defendant claims by virtue of the top or apex of the same being within its side lines as patented. The question is presented, whether the commissioner had power to issue a patent granting 300 feet on either side from the location point, or whether he was restricted to cede that quantity on either side of the center of the ledge actually located. The law, as has been stated, expressly limits the amount of surface to 300 feet on each side of the center of the ledge located; he had no authority or right to grant more than the law allows, and any disregard of this restriction renders his action, to such excess, as unauthorized, inoperative and void. The patent having been issued for 300 feet from the location point, instead of 300 feet from the center of the ledge located and claimed, as indicated at the shaft, on the diagram, contained in the patent, and the quantity of surface ground granted by the patent being 358 feet southerly from the ledge at the shaft, the patent is void and inoperative as to the excess of 58 feet. This removes all cause for contention between the parties as to the vein or lode in dispute.

The Judge says in conclusion: "Many witnesses were examined on either side, whose statements were quite conflicting in some respects as to vein formation, but I deem it unnecessary to review the testimony, as I conclude, for the reasons stated, and from all the proofs in the case, that the top or apex of the vein in dispute is in the Found Treasure claim, and not in that of the defendant." A decree will be entered for the plaintiff as prayed for.

Astronomical Society of the Pacific.

A meeting of the new Astronomical Society of the Pacific was held on Saturday evening last, Prof. E. S. Holden in the chair.

On motion the following applicants were admitted to membership: J. M. Selfridge, Wm. Alvord, A. O. Leuschner, Wm. F. Herrick, E. M. Bixby, H. T. Compton, C. F. Montealegre, Miss Rosa O'Halloran, W. Letts Oliver, E. B. Jordan, James G. Jones, Eugene Frost, C. Mitchell Grant, Prof. J. T. Wallace, T. P. Andrews, H. W. Harkness, C. F. Crocker, Henry Kahn and A. W. Ross, Jr.

A committee consisting of Messrs. Runyon, Soule and Tyler was appointed to nominate a board of 11 directors and a Committee on Publication.

The Committee on Nominations reported in favor of the following-named gentlemen as directors: E. J. Molera, Charles Burckhalter, J. M. Schaeberle, William Alvord, W. H. Lowden, W. C. Gibbs, Wm. M. Pierson, Dr. Wm. Boericke, Professor Frank Soule and C. Mitchell Grant.

The action of the committee was indorsed by unanimous vote.

Dr. W. A. Dewey, A. G. Treat and F. R. Ziel were elected a Committee on Publication.

The treasurer reported the receipts to date as $125.

A paper "On the Work of an Astronomical Society" was read by Prof. Holden. We shall shortly publish this in the PRESS.

After the regular meeting had adjourned the following officers were chosen by the Board of Directors:

Prof. E. S. Holden, President; Wm. M. Pierson, W. H. Lowden and Frank Soule, First, Second and Third Vice-Presidents; Charles Burckhalter and J. M. Schaeberle, Secretaries; and E. J. Molera, Treasurer. The Bank of California was designated as the custodian of the society's funds.

After appointing W. C. Gibbs and W. M. Pierson a Committee on Finance and electing Wm. Alvord a life member, the board adjourned.

The next meeting of the society will be held at the Lick Observatory, Mt. Hamilton, the last Saturday in May.

In addition to those elected at this meeting the society has the following members: E. J. Molera, A. P. Redington, Geo. W. Reed, C. L. Goddard, O. V. Lange, F. H. McConnell, S. C. Partridge, W. H. Lowden, E. W. Runyon, Wm. Boericke, W. A. Dewey, F. R. Ziel, Wm. M. Pierson, Chase Gitchell, Geo. Tasheira, V. J. A. Rey, A. J. Treat, J. H. Johnson, S. C. Passavant, W. B. Tyler, Wm. Irelan, C. Burckhalter, Ed. Gray, W. C. Gibbs, C. P. Grimwood, E. S. Holden, S. W. Burnham, J. M. Schaeberle, J. E. Keeler, E. E. Barnard, C. B. Hill, J. R. Jarboe, P. R. Jarboe, John Le Conte, I. Stringham, F. Soule, T. Guy Phelps, Arthur Rodgers, Wm. Norris, C. Webb Howard.

THE Mexican Government is reported to have realized over $50,000 in customs duties on goods taken to the Santa Clara mines, to say nothing of denouncement and other fees.

Maritime Protection.

The Samoan question has most undoubtedly awakened us to a keen realization of the unprotected condition of our country, which must result in an enlargement of the navy and the building for coast defense of free-board vessels of the Monitor system which proved so successful in our late civil war. The United States do not require a standing army, for the militia of each State and Territory is a large army within itself, and can be relied upon to put into the field at short notice several hundred thousand drilled men, which can be followed in an emergency with equally as many, if not more, citizen soldiers on the first call to arms. It is on the water that our country is sadly deficient, which has been made more plainly evident during the past three months.

The Parliament of Great Britain has just voted a large sum of money to the improvement and enlargement of her navy, which has been followed in a like manner by Germany and Russia, while each European nation has given liberal encouragement to the building of steamships capable of conversion into fast-sailing cruisers. It is the movements in the latter direction that must cause the heavy-armored ships of war to give place to the finest and fastest vessels constructors will be capable of building. This promised revolution in the building of war vessels has been brought about by the improved guns. And still the cry is for more formidable ship armament. It is not very long since an 80-ton gun was a monster; but this soon gave place to the 90-ton, which has been followed in turn by the 100 and 110 ton guns. The latter, it was concluded, were about as large as safety would admit of, but now these are threatened to be succeeded by guns of 150 tons, and even 200-ton guns are not at all unlikely to prove a success. Such guns no existing armored ship can withstand, and as for that, it is claimed that none can be built to successfully resist; therefore the greater necessity for speed and easy movement. The question naturally arises, with changed vessels of war, will not the armament also undergo a change? To this it is only reasonable to answer in the affirmative. The guns will probably change in the direction of less caliber and higher relative power, just as is being done with small arms for the infantry, as expressed by an exchange, to increase the range and secure a flatter trajectory with extended danger zone. At the same time, heavy armaments, dynamite guns, torpedoes and kindred warlike appliances, all will have their appropriate places. To provide plants on a scale commensurate with the demands of modern warfare must for years engage the attention and tax the best energies of all leading commercial powers, and the United States cannot afford to pose as an indifferent observer of events.

THE MARYLAND MINE.—We hear that in all probability a rich English syndicate will make all necessary development on the Maryland claims, Grass Valley. An expert in their employ is said to be in New York on his way to California to examine the mine. The Maryland adjoins the famous Idaho, and is believed by many to be equally rich, while it has a large amount of unworked ground. The mine would have been thoroughly worked long since, had its owners had sufficient capital. Grass Valley is the leading gold-mining district on this coast, and the Maryland may yet add greatly to its fame.

TRAINS commenced running to Tacoma on Monday, on the new coal road of the Central Pacific Improvement Co., from the coal mines of that company at Carbonado, 30 miles from Tacoma. A new road six miles long has been constructed from the mines to the main stem of the Northern Pacific, and a double track laid all the way to Tacoma, in order to bring a greater output there for vessels loading for San Francisco.

THE LICK TELESCOPE.—At the request of the University Regents, W. R. Warner, of the firm of Warner & Swasey of Cleveland, Ohio, manufacturers of the machinery and mountings of the Lick telescope, has been at Mt. Hamilton for the past week inspecting the adjustments of the instrument. He will probably make some minor changes and improvements in the machinery.

Crushing Lumps of Roasted Ore.

The extraction in trough-lixiviation is not produced by filtration; and the silver as well as the base-metal chlorides contained in the lumps of the roasted ore will not be extracted if the lumps are allowed to enter the trough together with the finer portion of the ore. In order to obtain good results it is necessary first to mash the lumps. An agitator will not perform the work rapidly enough, and some quick grinding machine has to be employed for this purpose. Figs. 1 and 2 show the construction of the *Kegelmuhle*, which is very effective on soft material, and is used in Europe for grinding coal. It is copied from Rittenger, with some slight alterations, which Mr. Ottokar Hoffmann made to adapt it to trough-lixiviation.

Top View of Fig. 3.

Fig. 5.

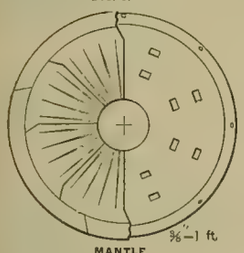

Fig. 6.

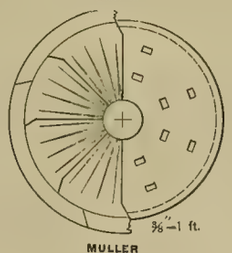

MACHINES FOR GRINDING SOFT ORE.

Figs. 3, 4. 5 and 6 represent another grinding machine for soft material, which is Mr. Hoffmann's own device. It is based on the principle of the *Kegelmuhle*. The mantle *m* is also stationary, but instead of being cylindrical is cone-shaped. The muller *f*, a flatter cone than the mantle, is inserted from below, and can be lowered or raised by the screw *g* for the purpose of regulating the fineness to which the lumps are intended to be mashed. Mantle and muller are provided with exchangeable shoes and dies. This mill has a larger working capacity than the *Kegelmuhle*, because the centrifugal force created by the rotation of the muller will greatly assist the discharge of the pulp, while in the *Kegelmuhle*, with an almost vertical discharge, the centrifugal force has no beneficial effect, but on the contrary acts against the full discharge of the pulp. Toward the center, shoes and dies are provided with teeth, while toward the periphery their surface is smooth.

The teeth cut the larger lumps, the smaller ones are mashed by the smooth part of the cones. Water and ore are charged through *A*, while the circular cast-iron trough *t* receives the pulp and conveys it to the base metal leach-trough *o*. The canvas strip *k* prevents the pulp from flying over the rim of the trough. The main portion of the roasted ore will be fine enough to pass through the mill without being affected, and only a small part will have to be mashed. For this reason, and on account of the softness of the wet material, large quantities of ore can be put through in 24 hours with but very little wear of the machine, which, in itself, is of simple and cheap construction.

Los Angeles Gold.—A dispatch from Los Angeles says: "The gold-hunting excitement is still maintained in this section. At present there seems to be an attempt to boom Monrovia by means similar to those used to induce immigration to Santa Clara. A mile and a half east of Monrovia are these gulches. These were visited to-day by a press representative who found nearly 200 men at work with picks and shovels. While there a dozen pans were washed, but the reporter could not detect the slightest sign of color, nor even a microscopic nugget.

Electrical Society.—The California Electrical Society held its regular monthly meeting on Monday. The evening was devoted to the "Relations of Experiences in Electrical Matters" by several of the members, in the course of which many facts of interest were elicited. W. O. Quimby spoke upon the introduction of the telegraph and the effort of the Mechanics' Institute of San Francisco to procure the telephone from Prof. Bell for exhibition in this city in 1877, and also the introduction of the electric light in Calif in 1882. F. M. Speed urged the necessity for concentration of effort in electrical specialties, and argued that diffused effort defeated success. President Keith related his experience in installing the first electric-light plant at the Madison Square Gardens, New York, in 1879, and said that it then took about 100-horse power to run 16 lights, which now can be operated by improved dynamos with less than 16 horse power.

A Silver mine has been located nine miles south of Bagdad, on the Atlantic & Pacific road, and six miles east from Daggett. The ore is four feet below the surface and yields 2600 ounces silver to the ton. The assays made show that it is one of the richest silver mines in California. Crowds are going to the mines. The excitement in San Bernardino is general and is increasing.

Lake County people are urging the Southern Pacific Company to build a line into Lake county from Rutherford, on its Calistoga branch, via Chiles and Pope valleys.

The Late Arthur Nahl.

Arthur Nahl, well known all over the State as a pioneer Californian artist, died suddenly of heart disease on the ferry-boat, while on his way to his home in Alameda on Monday last. He came to America from Hesse-Cassel 40 years ago, and has resided most of this time in San Francisco. Mr. Nahl sketched and painted many scenes of early California life, and drew for the magazines and pictorials of pioneer San Francisco, numbers of illustrations of scenes and incidents of those times. He excelled in animal and figure painting, and of late years has devoted his brush mainly to portraiture, in which he was very successful. His rare gallery, embracing a number of paintings by the "Old Masters," among which were portraits of Mr. Nahl's kinsmen who were notable artists for several generations, is one that for years has attracted attention through private exhibition to many of our art-loving people. He leaves a remarkable gallery.

Mr. Nahl was always very fond of athletics, and he and his brother had a small gymnasium at their home, on Telegraph hill, long before there were any public institutions of the kind in this city. The interest shown in this induced him to take steps to organize a club, and the Olympic club was the result, he having been the founder of that flourishing institution. For many years he was a leading member, though of late he has taken no active part.

Mr. Nahl had a host of warm friends. He was a good man and citizen, an able artist, industrious and steady, earning the respect of all with whom he came in contact. It is rare to see one hold so well-known a leading position for so long. Every one spoke well of him and his work. His name is linked with the history and development of California. Such men are rarely met, and their places, once vacant, are seldom filled. Mr. Nahl leaves a widow and six children. He has resided in Alameda for 20 years, living in a handsome home which his industry had provided for his family.

Ozocerite.

Ozocerite is a peculiar mineral wax, a good deposit of which was found in Utah several years since, the only one of the kind thus far discovered in the United States. In another column is given an item which was published in the Eastern States, to the effect that it is only found elsewhere at Galicia, Austria. This is incorrect, for there are large deposits in Russia, where it has been utilized for making ties on the Transcaspian railroad. Notwithstanding the high temperature, which reached 140° F., the ties retain their hardness and shape. These ties are used all along the road, except at the ends and centers of the rail, where wooden ties are employed. A saving of $800 a mile is effected by use of this material.

The substance is also found at Slanik, Moldavia, and at the foot of the Carpathian mountains. The Turkish ozocerite is usually considered the best. It is like wax or spermaceti in appearance and consistency, ranging in color from an impure white to black, and is frequently brown or green. There are also deposits in Austria. Though the deposits in Utah have been known since 1877, it is only this year that active steps have been taken to utilize the product, a company having been formed for the purpose.

Manuel Eyre vs. Mining Companies.—Judge Hunt has overruled the demurrer of the defendants in the eight actions brought by Manuel Eyre against the directors of eight mining companies to recover $1000 damages in each case for failure to post in the offices of the respective companies the amount of receipts and disbursements thereof, as required by law. Ten days were given to defendants in which to file answers in each case. Now the matters must be tried upon merits.

Academy of Sciences.—At the meeting of the Academy of Sciences Monday, H. R. Taylor contributed a stone sinker, evidently of Indian manufacture, which was found in a shell-mound near Alameda. As there was no regular paper prepared for the evening, Frederick Goetzkow gave an informal talk on automatic water-meters. The meter recently patented by him is described in another column of this number of the Press.

Coast Industrial Notes.

A $25,000 PLANING-MILL is being erected at West Berkeley.

THE Alvarado Beet-Sugar Refinery has been sold for $150,000 to the Alameda Sugar Co.

A COMPANY to manufacture terra cotta and pressed brick has been organized at Vallejo.

THE Coronado hotel, San Diego, is to use the Avery gas patents, to supply the hotel with gas.

THE Pacific Granite Co. has been organized in San Diego, to work the granite quarry in Temecula canyon.

OWING to the great use of the twine binder in harvesting, the consumption of hemp and similar fibers has increased 25 per cent during the last year.

THE California Tallow Works have a growing industry in charge. Large quantities are consumed here, and there is a considerable export to Central America and elsewhere.

THE San Francisco Wave-Power Co. has been authorized by the supervisors to use 20,000 square feet of the city cemetery for the purpose of constructing reservoirs therein.

BY the burning of the great Anaconda copper smelter at Butte, Mon., about 1200 men are thrown out of employment at the Anaconda, while at Butte 800 miners are paid off.

HENRY BEST of Sutter county has ordered a steam-plowing apparatus, which is expected to plow 75 acres in 24 hours, at a cost of $25 for all expenses. The cost of the outfit is $4500.

THE mills of the San Diego Iron Works at Roseville turned out their first product March 25th in the shape of galvanized-iron wire cloth. The wire and nail departments will be opened soon.

AT the end of March the Pacific Coast Steamship Company discharged 16 painters, calkers and carpenters. The reduction in the force is due to dull times and a consequent falling off in the carrying trade.

AN English paper states that the modern labor-saving machinery introduced into foundries and machine shops has resulted in 50 men producing as many castings as were formerly turned out by 200 men.

THE plans for the new passenger depot, to be erected at Third and Townsend streets, are now completed, and work is to be begun immediately. The building will be two stories high, and will cost about $25,000.

COLLECTOR HAGER has issued a warning to all persons engaged in fishing in Alaskan waters not to construct dams or other obstructions in the rivers there. He has done this in accordance with instructions from Washington.

PREPARATIONS are being made here for establishing half a dozen new salmon canneries along the Alaska coast during the coming season. It is not thought that there will be any important additions to the Columbia or Sacramento river canneries.

RECENT additions to the many harness factories of this city have increased the number to 35. These shops employ about 500 men and boys, and will turn out about $1,500,000 worth of manufactures this year if trade continues to increase at the present rate.

THE planing-mills, box factories and iron foundries are among the busiest of the local industrial works. Boiler-making for coast steam craft has been a prominent feature of the iron trade here for a few months past, and it will be carried on extensively this season.

E. J. BRICKELL and W. H. Kruger, the well-known capitalists composing the Truckee Lumber Company, are going to engage extensively in the ice business. They own 18,000 acres of land in the heart of the ice belt, containing locations for over 50 good ice ponds.

THE proclamation issued by President Harrison against unlawful sealing expeditions is causing much excitement among the independent sealers. It is certain that the United States revenue cutters will make seizures of all vessels illegally sealing in the Behring sea.

ORDERS have been received at the Mare Island navy-yard to proceed with work upon the new stone dock, the last Congress having appropriated $80,000 to complete the structure, which has been 17 years in course of construction and has cost upward of $2,000,000.

MR. W. K. GIRD has found a deposit of bituminous rock on the Chino ranch, San Bernardino county. The deposit is in Brea canyon, in close proximity to the surveyed line of the narrow-gauge railroad, which will at once be extended to the scene of this important find.

THE steam schooner Selmo was launched from Dickey Bros.' yard recently. She is a 70-ton vessel and was built for the Pacific Steam Whaling Company. The engines for the new vessel will be placed by the Union Iron Works, and it is expected that she will attain a rate of speed of 11 knots an hour.

THE rolling-mills of the Judson Works opened Monday, and everything is now running smoothly. All of the men who were a short time ago thrown out of employment by the sudden closing of the mills have been taken back, and are now engaged in their old places, at their former wages.

THE Victoria Lumber and Manufacturing Company, composed of one president from Victoria, B. C., and three lumbermen of Hudson, Wis., with a capital of $1,000,000, is securing a special Act of incorporation. The company will erect mills at Esquimalt, Chemainus and Connox for local and export trade.

THE Sanbedrin Mill & Lumber Company have recently contracted with the Vulcan Iron Works for the machinery for their new sawmill, to cut about 50,000 feet of lumber per day; and have also selected a 60 inch heavy "Vulcan" gang edger, a set of heavy "Vulcan" fractional screw head blocks; also an 8x10 "Campbell" steam feed.

THE silver bars made at the Selby Lead & Smelting Co.'s works are 12 inches long, 5 inches wide and 4½ inches deep, averaging from .998 to .999 in fineness, valued at about $1250 per bar. Something like 21,400 of these have been produced in 3½ years, the number in gold being about 2135, measuring 8 inches long, 4 inches wide and 4 inches deep, averaging about $22,000 in each.

ONE of the local box manufacturers who has made a success in the fruit-box line will soon add a large shop with new machinery to his works. The outlook for the season in this line is very bright, and there will soon be great activity. There are about 500 men now employed in making boxes in this city, taking the year right through, and over 15,000,000 feet of lumber are used in this way.

THE 100,000 fur seals, as taken by the Alaska Commercial Co., bring nearly $2,000,000 each year, and for this privilege the fee to the United States Government is the small sum of $296,286.82—being the exact average amount paid by the Alaska Commercial Co., and to be paid by them each year, as claimed by the Alaska Commercial Co., during the 20 years of their lease.

AN Eastern manufacturer of cuffs and collars has lately been surveying the field here with a view to establishing a factory for making goods in his line. He finds there is a good opening here in one respect, as there is no regular manufactory of either collars or cuffs in San Francisco. The only drawback is that the competition of Eastern manufacturers would be very great at first.

AT a recent meeting of the Marine Engineers in this city, a subject of discussion was the schedule of wages to be paid the engineers and assistants on the Alaska fishing steamers. The wages offered by the vessel-owners are $100 per month for engineers and $80 for assistants. This did not meet the views of the union, who finally fixed $125 and $90 as the wages that should be expected. This rate is to prevail until a new schedule shall have been adopted.

THE final order in the disincorporation of the Watsonville Mill and Lumber Co. has been signed by Judge McCann, and the corporation has gone out of existence. During its life it employed hundreds of men and expended hundreds of thousands of dollars for labor and supplies. The Watsonville Mill and Lumber Co. was one of the oldest lumber companies in the county, and when its mills were cutting the Pajaro redwoods it was the largest sawmill company in Santa Cruz county.

MARTIN HOLJE has been making glue here for a number of years. He is the proprietor of the California Glue Works at Venezuela and Potomac streets. He makes from 50,000 to 100,000 pounds per month of pure hide glue. The San Francisco Glue Works are at Santa Clara and Wisconsin streets. There is another small factory in another part of the city. These factories employ about 50 and make 300 tons glue and 80,000 gallons neatsfoot oil per annum, of a value of $110,000.

THE Inyo Marble Company now split blocks of marble with gunpowder. A hole is drilled half through the block and notches are cut on each side of this in the direction in which the block is to be split. Black powder is poured loosely into the hole and the fuse inserted; a piece of wadding is then forced into the hole about a foot, leaving a considerable air space between that and the powder, and tamping placed on top of it. On firing the blast the marble block is divided as neatly as could be desired.

THE Watsonville *Pajaronian* says: But two sawmills will run in this township this year—the Rider mill, in the Game Cock canyon, and White & DeHart's mill, east of the San Jose toll road. The end of the lumbering business in this part of the county is but a few years distant, and yet 20 years ago it seemed as if the redwood forests on the Pajaro slope of the Santa Cruz mountains would outlast the oldest inhabitants. Improved mill machinery and the large demand for lumber created by railroad extensions have eaten out the Pajaro redwoods. The mills named above expect to start up before the middle of April if the weather does not prevent. At each mill there is much felled timber for the season's run.

ONE bill of importance passed by the recent Legislature, and which has since been signed by the Governor, empowers the Board of Harbor Commissioners to construct and operate creosoting works for the protection of piles used in the building of wharves belonging to the State. Thirty thousand dollars has been appropriated for this purpose, and the works will be located on State property somewhere in the northern portion of the city. The process to be used is not covered by a patent.

THE openings in the quarry of the Inyo Marble Co. allow the extraction of blocks 4000 cubic feet, in length 25 feet by 10 or 12 feet. The reduction of such solid masses to useful shape becomes a mere matter of machinery and convenience. Negotiations are under way with the Inyo (Eastside) Canal Co. for power at the "drop-off" on their line, with the view of locating works there. The railroad company have completed the new 3000-foot switch from the main track to the present works and the quarry dumps.

THE Giant Powder Company of San Francisco has just bought 180 acres of land near Clipper Gap station, Placer Co., including the Hicks tract and a portion of the Hahn ranch. Their land includes that which is traversed by the Bear river ditch where it makes a rapid descent just above the old school-building on the Applegate road. This descent will be utilized in furnishing power for their works. They expect to begin the erection of their buildings without loss of time for the manufacture of black powder, and will employ at least 50 men in their business. The Canal Co. will furnish the power for their machinery.

ON the 1st inst. there was launched at the foot of Folsom street a new steam launch for the Alaska Packing Company. She was built by the Atlas Iron Works and is a pretty little craft. Her dimensions are: Length, 25 feet, beam 8 feet, depth of hold 6 feet. She is fitted with compound engines, her high-pressure cylinder being 6½ inches, low pressure 10½ inches, with a 10-inch stroke. The new steamer is fitted with J. B. Jardine's patent condenser, which, consisting as it does of a series of metal tubes under the vessel's counter, looks something like a huge gridiron. It takes the place of the condenser usually used on steamers, and, it is claimed, saves considerable in weight, both of material and water.

OAKUM has been imported here for 40 years. The imports for 1853 were 2330 bales. For the past quarter of a century these imports have been 85,500 bales, or an average of 3400 bales per annum. The extremes have been 1100 to 9800 bales. The last-named was the quantity imported in 1866. Notwithstanding these supplies, it has been found profitable to make oakum here, and the business has been carried on many years by Samuel F. Weeks. The local product has increased from 1000 to 10,000 bales per annum. In the past quarter of a century prices have varied from $3 to $9 per bale. Current rates are $4 to $5. The local product last year was valued at $40,000.

THIS is the time of the year when people buy new furniture, and it is consequently the best season for the bedding and upholstering men. At each of the dozen factories in this city where this work is done there is a scene of activity. Fully 200 men and boys are employed in this work in San Francisco. Most of the factories are small, and in some of them only four or five people are employed, while in others the proprietor and his one boy do all of the work. In the small factories much of the upholstery work is done on old frames that are to be newly upholstered. So cheaply is work done here now that there is little chance for Eastern factories to make much headway in the field. What little work now comes to California from the East is a mere bagatelle. The business is growing rapidly, and it is estimated that the value of the manufactures here this year will reach $1,000,000.

FROM a modest beginning in 1862, the San Francisco Cordage Company has grown to be one of the largest and best equipped in the country. Improvements have been added from time to time as needed. The works of the San Francisco Cordage Co. are at South San Francisco. The grounds are ample, the buildings extensive and well constructed and the machinery first-class. The hemp is brought from the Philippine islands at the rate of about 3000 tons per annum. There are 150 to 160 employes, and the value of the product is $600,000 per annum. The business has been attended with perils common to all local industries. There has been continuous competition from Eastern factories, and the prejudice in favor of this product on the part of some, as well as the local opposition for a few years. Despite these and other untoward circumstances, the San Francisco Cordage Company has never ceased operation, except for necessary repairs. The San Francisco Cordage Co. has recently put upon the market a "new-process" rope, which is guaranteed equal to Sisal rope. This is four cents per pound cheaper than manilla, which is an important difference. The new-process rope is quoted at 13½ cents for 1¼-inch and upward, 14 cents for 12-thread, 14½ cents for 6 and 9 thread; bale-rope, 2, 3, 4, 5 and 6 thread, 13 cents.

THE 17th annual session of the California College of Pharmacy and Department of Pharmacy of the University of California commenced Monday evening, the opening exercises being held in the college building at 113 Fulton street. A large number of pupils were present, the class this year numbering between 90 and 100.

THE cruiser Charleston is still upon the dry-dock at the Union Iron Works. Several hundred men are at work putting the finishing touches to her exterior and interior. This week the propeller blades were placed in position and steam made in her boilers to test their completeness. An immense amount of work is done every day, but it will be two weeks before the trial trip can be made. She will be taken down the coast, and, on her return from the trip, will go to Mare Island to receive her armament.

T. D. MCKNIGHT, General Freight Agent of the Northern Pacific Railroad Co., says that owing to the increase in the rate on canned goods from $1 to $1.20 per hundred, the entire business in that line was being transferred from the railroad companies to sailing vessels clearing for Atlantic ports by way of the Horn. The hatches of the ship Jabez Howes were closed down on over 8000 cases of canned fruits from one prominent house in this city, and 200,000 cases are expected to follow from various sources during the present season. These shipments have heretofore been handled by rail, and represent some 500 carloads of freight. The rate by sailing vessel is now less than one-half that by rail, and extensive shippers naturally avail themselves of it. The fact of the matter is, the competition on canned goods in Eastern markets is so spirited that shippers cannot afford to pay such a high tariff.

THE bill passed by the recent Legislature compels employers to provide seats for female employes, to be used when the women and girls are not actually at work. The law went into effect on February 8th last, but since that time no steps have been taken by the firms of San Francisco, who never had seats for the girls, to comply with the law. The Labor Commissioner is sending out circulars to employers, calling their attention to the new law. The main sections of the law are as follows:

SECTION 5. Every person, firm or corporation employing females in any manufacturing, mechanical or mercantile establishment shall provide *suitable seats* for the use of females so employed, and shall permit the use of such seats by them when they are not necessarily engaged in the active duties for which they are employed.

Sec. 6. Any person or corporation violating any of the provisions of this Act shall be punished by a fine of not less than fifty nor more than one hundred dollars for each offense.

Sec. 7. It shall be the duty of the Commissioner of the Bureau of Labor Statistics to enforce the provisions of this Act.

A GLANCE at our rank among the cities of the country in those conditions which bear upon the utilizing of pipe and wire, boiler and dynamo, wonderfully hightens the parallel between this system and our profitable cable roads. San Francisco ranks in:

Population	9th
Manufacturing concerns	8th
Capital employed	10th
Hands employed	11th
Wages paid	10th
Value of product	9th
In number of establishments in proportion to population	1st
In average hands to each establishment	17th

It will be seen, then, that to supply our own wants and the needs of our commerce for its exchanges, we have already been urged to the founding of more separate manufacturing plants than any other city in the Union, in proportion to population. Added facilities mean increase in plant and product, just as the extension of our cable-road system meant an extension of population into new districts and an increase in travel.

THE Inyo *Independent* says: There are quite a number of men employed at the soda works. The new windmill for pumping the lake water into vats works quite successfully. Several large sheds are being erected for storing the soda from the weather. This enterprise has passed beyond the experimental stage and is on a firm basis. Of course, the industry is yet in its infancy and will assume much larger proportions, the fact being established that the work can be continued at a profit. When better railroad facilities are secured, extensive improvements will be made. Messrs. Conn & Trudo have located 1120 acres of borax land in Saline valley, and will work the property extensively. A wagon-road has been built to connect with the Big Pine road to Deep Spring. Considerable machinery has been shipped in and buildings are being erected. They have named the settlement Ferndale. The industry promises to be of considerable importance and will still further increase the demand for valley products. A number of men will be employed at the works, and teams will be required to haul the borax to the railroad.

OUR LUMBER INTERESTS.

The Lumber Trade.

The financial depression in the southern part of California and the comparative quiet in building circles in this city so greatly reduced the demand for lumber during the past year that the mills on Puget Sound have been compelled to stop work during a portion of the time for the past month in order to reduce the large accumulation of lumber in the mill yards. The cut has been reduced some six or seven millions of feet by this temporary shut-down. The lumber which for a year and more had been in great demand in Los Angeles and San Diego counties began to stop in this city during the latter portion of last summer in such quantities as to fill the San Francisco yards with so large a surplus as to reduce the price below any profitable rate for production. The highest point in prices was reached on the 1st of August last. Then the decline commenced, until lumber reached about the lowest price ever noted in this market. The boom initiated by the completion of the Northern Pacific railroad created a large local demand, which kept the mills running for a time; but even that extra demand soon failed to keep up with the production, so that a shut-down became a necessity.

The result of the shortened supply has been an advance in prices. February 1st prices were advanced by dealers from $12 to $14 per thousand, with cargo price at $13; and on the 14th inst. the pine-men made an advance of $2. The next day the retailers advanced $3 per thousand, and the redwood-men are also, at this present writing, contemplating an advance in their specialty. The lumbermen hold that the advance has been made because they have been unable to make a living at old prices, and that it should be advanced to $18 as soon as conditions will admit. At present, low prices must rule. It is claimed that freights are so high at the present time that California lumber is shut out from distant markets, and trade is necessarily confined to home consumers. As soon as more ships and cheaper freight can be obtained, lumber can be sent to Australia, South America, and other distant points, and prices will take a further advance.

Timber Lands in Fresno.

There will soon be a railroad from Fresno into the timber belt in the eastern portion of that county. In view of this, according to the Stockton *Mail*, many tracts of land are being taken up in the timber belt from Sonora to Fresno under the Timber Land Act. Parties from San Francisco are the principal speculators, in companies of from 25 to 30 members, and buying adjacent lands. Some 30,000 acres or more have been entered since October 1st of last year, and there have been filings on many thousands of additional acres. Entries have been made all along the line from Tuolumne to Fresno county.

The cost of the land is $2 50 an acre, and applicants can have any number of acres up to 160, but not in excess of 160. The acres must be contiguous; that is to say, the applicant cannot pick out small tracts here and there aggregating the maximum number. He is not allowed to make more than one entry, and consequently if he takes 40 acres instead of 160 it "lets him out" of the remaining 120 acres forever after.

In order to acquire timber land, the applicant must be 21 years of age or over. Unmarried women can buy the land in their own names; and married women can also purchase tracts for themselves, provided they pay for the property out of their separate possessions—in other words, if they buy it with money to which the husband has no constructive claim in law.

In acquiring these lands, applicants must go through certain forms. They must visit the tracts which they wish to purchase, inspect them, appear at the land office, have a date set for proving up and advertise for two weeks. The applicant appears on the appointed date with two witnesses, proves that the desired tracts are timber land, and pays the price of $2 50 an acre.

ORIGIN OF OUR ENGLISH LUMBER TRADE.—According to a late interview with David Evans of Humboldt county, a member of the firm of C. A. Hooper & Co., the real traffic in lumber with Great Britain began in 1885. In that year, said Mr. Evans, my company alone exported 7,000,000 feet to that country. Since that time we have averaged a little over 3,000,000 feet annually. The cause of the rise to 7,000,000 feet in 1885 and the subsequent decline to 3,000,000 feet was the Edinburgh Exposition. The demand took date from a magnificent display in the Edinburgh Exposition of 1884. Humboldt county was represented there by a large display of redwood in charge of a competent California exhibitor. The redwood was exhibited in all its various stages of manufacture and its virtues made known, which resulted in the large sale of 7,000,000 feet in 1885. Since that time the trade has been steady, but not so great as during the Exhibition year. Mr. Evans added that during the Exhibition at Edinburgh there were many of the merchants who purchased Humboldt lumber from the agent there in direct sales, and that if the London exhibition could be effected, the lumber interests of California would receive a great boom in the direction of exports to England. As the present time timber is still there indirectly and at a much higher rate, which necessarily limits the demand.

IMMENSE FRANCHISES INVOLVED.—In the case of the St. Catherines Lumber Co. vs. the Dominion Government, the British Privy Council in London has rendered a decision against the Government. The value of the license granted to the St. Catherines Lumber Company alone is placed at $5,000,000, and the titles to hundreds of thousands of square miles are upset. It is estimated that the value of the licenses involved will not fall short of $50,000,000. These leases are to cut timber, and a number of American capitalists have invested heavily in them. Claims against the Dominion Government will probably be prosecuted.

MINNEAPOLIS LUMBER MILLS in the present season, have turned out 332,928 604 feet of lumber, 106 736 150 shingles, 73,173,320 lath and 731 850 pickets. In 1887 the cut was: 220,822 974 feet of lumber, 69,565 050 shingles and 42 936,611 lath. Again in 1888 of 112,105,630 feet of lumber, 37 171,100 shingles and 30,236,708 lath. In the amount of lumber this beats the record of any previous year, except 1882, when 314 363,166 feet were cut.

GIANTS OF THE FOREST.—A British Columbia paper says: "This is the veritable land of the giants of the forest, and one of the first things that strikes strangers is the enormous size of the trees. But in spite of their exclamations of wonder, very few of them really comprehend how large the trees really are. A stick of timber was cut the other day at the Hastings mill which was 106 feet long and 24 inches square. There were sawed out of the log 12,000 feet of cedar lumber, weighing 30 tons."

THE FORESTS OF WASHINGTON TERRITORY.—The Secretary of the Interior in his recent report to Congress says that the forests of Washington Territory furnished 320,000,000 feet of lumber, 69,000,000 lath and 50,000,000 shingles during the last fiscal year, of which over two-thirds was shipped for foreign consumption. The capacity of the sawmills of that Territory he placed at 1,043,596,000 feet.

THE Santa Rosa *Republican* of March 24th says: Work on the redwood lumber-mills will not be started for some time, owing to the bad condition of the roads.

MICHIGAN LOGGING STOCK.—A careful estimate of logging stock for the coming season shows the cut will reach 140,000,000 feet of lumber.

LAST YEAR Louisiana produced 450,000,000 feet of lumber, an increase of 800 per cent since 1880.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

ASSESSMENT NOTICE.

Gray Eagle Mining Company.—Location of principal place of business San Francisco, California. Location of works, Placer County, California.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 10th day of March 1889, an assessment, No. 12, of Five Cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Room 9, No 327 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1889, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 14th day of May, 1889, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.

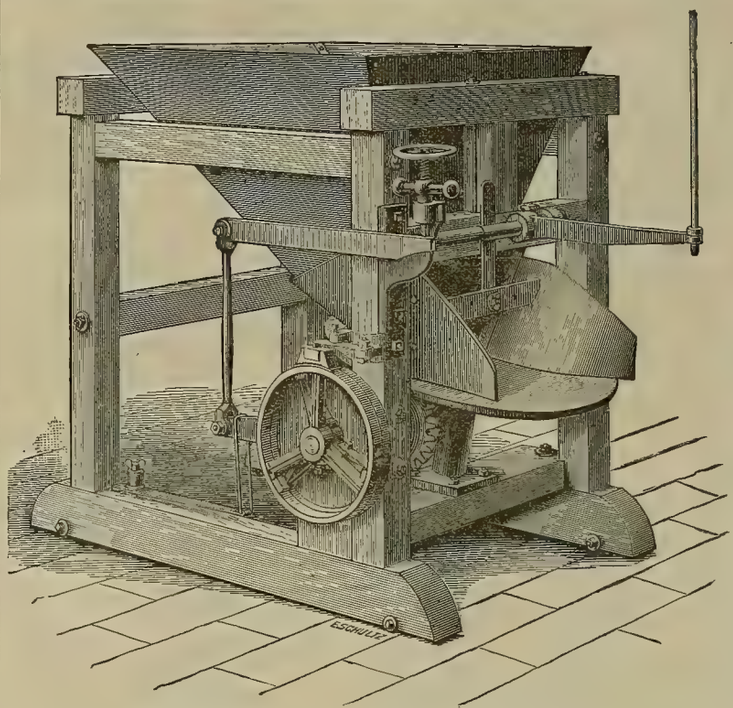
—THE—

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 FREMONT STREET, SAN FRANCISCO, CAL.



"HENDY" IMPROVED "CHALLENGE" ORE FEEDER.

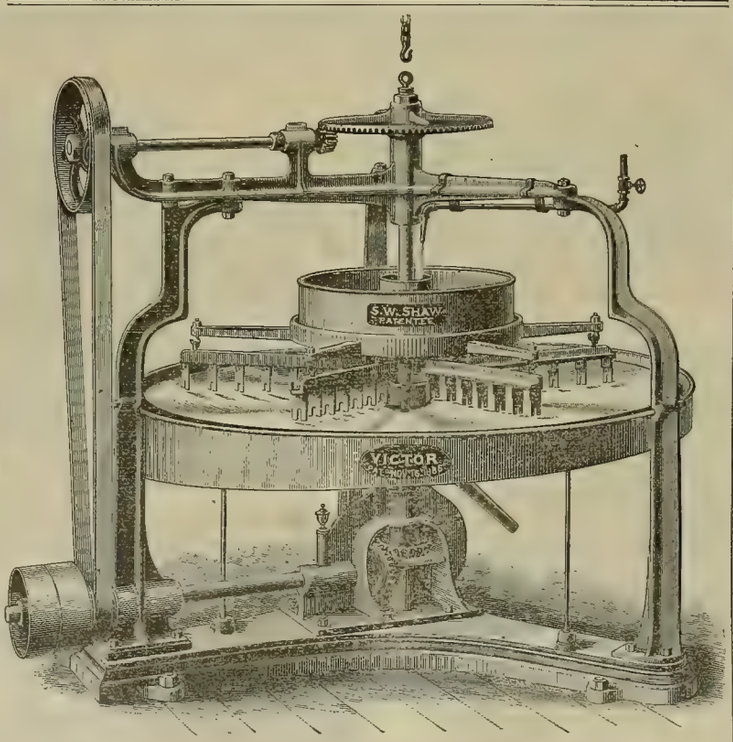
The **best form of Feeder ever devised,** and pronounced by reputable mining men to be far superior to any form of "Roller" Feeder manufactured. We refer to the following gentlemen who have furnished us with testimonial letters to the above effect, which can be seen at our office, viz.:

N. W. CROCKER, Supt. Bunker Hill Gold Mining Co., Amador City, Cal.
W. G. ROBERTS, Greenwood, El Dorado Co., Cal.
D. C. WICKHAM, Taylor Mine, Greenwood, Cal.
J. R. TREGLOAN, Supt. South Spring Hill Gold Mining Co., Amador City, Cal.

WE ARE MANUFACTURERS OF THE

"CHALLENGE," "STANFORD," "TULLOCK," & "ROLLER" FEEDERS,

And will furnish descriptive Catalogues and quote prices upon application.



THE VICTOR CONCENTRATOR

Having passed the experimental stage, is now offered to the consideration of the mining public, in full confidence that it will meet satisfactorily all reasonable requirements. In operation it is unlike any other machine of its class. The concave disc having a rotary reciprocal motion, causing the waste sands to flow over its periphery continuously, while the sulphurets are also drawn continuously through its center, the whole process being automatic and complete. The Batea in the hands of an expert is known to be the nearest to perfection for concentration. This is the principle upon which this machine works. The advantages gained are:

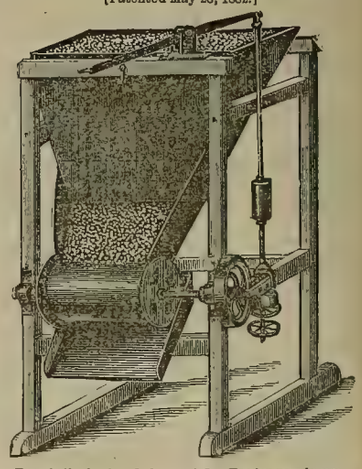
1. Greater capacity with more perfect work.
2. Simplicity of construction and management.
3. When used as an amalgamator it has no equal.
4. The first cost is less than other machines of much less capacity.
5. The shipping weight is less than 1000 pounds.

Mine owners and millmen are invited to carefully examine the Victor before deciding upon their concentrating works. Address

S. W. SHAW, or N. W. SPAULDING,
17 and 19 Fremont Street, SAN FRANCISCO.

THE ROLLER ORE FEEDER

[Patented May 28, 1882.]



This is the best and cheapest Ore Feeder now in use.

It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,

Sole Manufacturers,

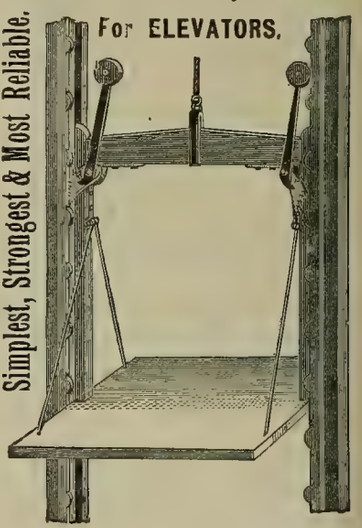
827 First Street. San Francisco, Cal.

B. E HENRIKSEN'S PATENT

Automatic Safety Clutch

For ELEVATORS.

Simplest, Strongest & Most Reliable.



Constructed upon Scientific Principles.

Operates and Sets Automatically and Ever Ready for Service.

Entirely free from all springs, pawls, triggers, governors and other unreliable parts likely to stiffen, corrode or gum up.

ALWAYS IN FULL SIGHT, BUT NEVER REQUIRING ANY ATTENTION.

Has been practically tested in six actual elevator accidents and saved 51 person from injuries and death.

SILVER MEDALS awarded by the Mechanics' Institute in 1880, 1882 and 1883. SEMI-CENTENNIAL GOLD MEDAL awarded by the American Institute of New York, Dec. 3, 1887. Apply to

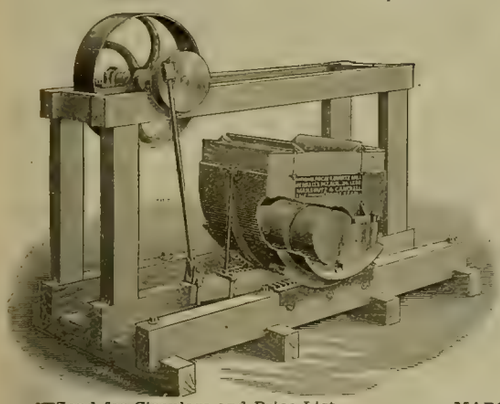
KENDALL'S PATENT, AUGUST 24, 1886.

CAPACITY, 12 Tons in 24 Hours. 3 H. P.

MARSHUTZ & CANTRELL, Sole Manufacturers.



The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

☞Send for Circulars and Price List. MARSHUTZ & CANTRELL.

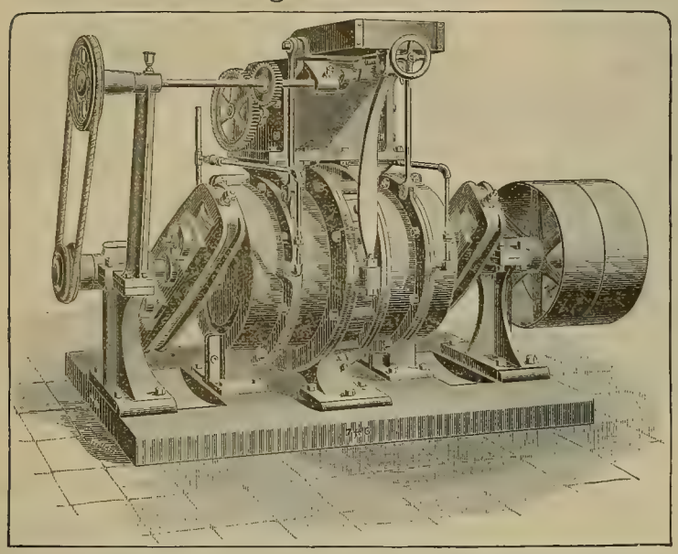
FRISBEE WET MILL.

This Mill, with a weight of less than 9000 pounds, has a capacity of three tons per hour of hard quartz to 40 mesh; has been thoroughly tested; we guarantee its work as represented, and we will give long time trial.



IT HAS NO MORE WEARING PARTS THAN CORNISH ROLLS,

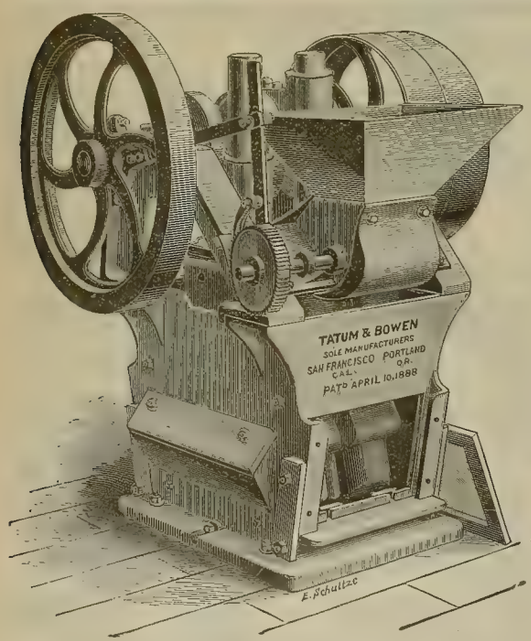
And renewals will not cost over one-half as much as for stamps. Will run empty, or with small amount of ore without injury. The attention of parties having Cement Gravel is called to this Mill, as it will run 100 tons per day to No. 8 mesh; 30 to 35 H. P.

OUR DRY MILLS are the most economical ever built, and are extensively used with record of several years. No grinding in pans. Mill finishes to any fineness desired.

FRISBEE-LUCOP MILL COMPANY,

GIDEON FRISBEE, Manager, - - - 32 First Street, San Francisco.

HOOKER & LAWRENCE, Gen'l Ag'ts, 145 Broadway, New York.



—THE—

PERFECTED DOUBLE Economic Quartz Mill.

Attached to each Mill is an effective

Automatic Ore Feeder.

THE CRUSHING is done by the rapid rocking movement in OPPOSITE DIRECTIONS of two heavy castings, the bottoms of which are slightly circular in form, and each provided with four shoes.

The Mill is a closer Gold-Saver and catches a larger percentage of the Clean-up in the Battery than any other Mill.

It costs less, in proportion to what it will do, than any other mill. There are no working parts to buy for it, no matter how long it is used, except shoes and dies. Capacity of Mill, 6 to 10 tons per day. Weight of Mill, complete, 6400 pounds.

We manufacture, to go with the Mill, an

IMPROVED ROCK BREAKER.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, April 4, 1889.

The volume of goods going out on order, and also by personal buying, shows a steady increase, yet the purchases indicate a conservative course. The money market shows a growing ease, with more funds offering on the market, chiefly from outside sources. The sluggish money market, more than anything else, shows an absence of any speculative movement. Receipts of treasure the past week by sea were as follows: Silver bullion, $92,594; coin, $10,192. The internal revenue collections for this district in last month aggregated $125,875. San Francisco clearing-house exchanges in March were $67,011,264, against $65,697,735 in March, 1888, showing a slight gain for this year. The exchanges for the first quarter of 1889 were $195,113,723, against $192,529,140 for the first quarter of 1888, a gain thus far this year of $2,584,583. The coinage of the San Francisco mint last month was as follows: Double eagles, $1,120,000; eagles, $380,000; dimes, $255; total, $1,500,255.

The steamship City of Peking, hence for China, March 28th, took out the following treasure: To Hongkong, Mexican dollars, 136,632; silver bullion, $66,000; gold coin, $1462. Total, $204,094. To Hiogo, silver bullion, $136,700.

NEW YORK, April 4.—Quicksilver has ruled fairly steady. Refined borax is firm. Pig lead has met with fair sales at a slight advance; the closing is easier. Tin has moved off more freely, causing a firmer tone to obtain. Copper is quiet and indefinite. Consumers think the existing complications will give prices an advantage in the near future, while holders feel that there will be a recovery of tone. In iron there appears to be a steadier tone.

SILVER—The market in sympathy with prices abroad, weakened off up to yesterday, when a slight advance was noted. Local values now keep more in accord with New York, with perhaps at times from one-twentieth to one-tenth advance obtainable here. There are three causes assigned for the decline in silver: First, the suspension of the Comptoir d'Escompte drew out of the China market quite an important factor, whose movements had a decided bearing on silver. Second, the failure of the copper syndicate, and also the revolutionary character of the movements in France have created a feeling of uneasiness in monetary circles abroad. Third, the Indian council bills are, as usual at this time of the year, offering quite freely on the London market.

MEXICAN DOLLARS—The market has held up fairly well considering the decline in silver. The supply here is reported to be light. Quotable according to quality at 92¾ to 93¼c.

QUICKSILVER—Receipts the past week were as follows: J. B. Randol, 310 flasks; Parrott & Co., 40; Haas Bros., 110; W. B. Bradford, 54; H. M. Newhall & Co., 30; A. Abbey, 45; total, 589. The market is steadier, with inside quotations dropped. The demand has improved.

TIN—The market for pig is unchanged. For tinplate spot is very strong, as the Scottish Dales has not put in an appearance yet. The demand, pending fresh importations, is confined to actual, immediate wants. There was shipped the past week by sea to British Columbia, 59,397 pounds of tinplate.

LEAD—The market is quiet, at steady prices. The usual spring trade is reported. There was shipped by sea the past week 5045 lbs. of pig to Victoria.

BORAX—The market is quiet but steady. Receipts the past week aggregate 1874 ctls., and shipments, 55.391 lbs., made as follows: To Pittsburg, Pa., 23,609; New York, 30,211; and Mexico, 1571.

LIME—The market is without change. Receipts the past week aggregated 4463 barrels.

COPPER—Cable advices indicate a favorable settlement of the affairs of the late syndicate, and that a new one will be formed embracing elements of strength, which were lacking in the old to make a success. Until order is brought out of the present chaotic condition of the markets at the East and abroad, quotations are more or less nominal.

PIG IRON—Imports the past week were 600 tons from England. The local market is without any essential change to note. Consumers still operate only for immediate wants, while importers do not appear disposed to press the market.

COAL—Imports the past week were as follows: Overland, 110 tons; Cedar River, 2500; Renton coal, 2200; Australian, 3498; Scotch Splint, 1916; Nanaimo, 3694; Port Moody, 2200; Seattle, 6850; Departure Bay, 7200; total, 30,058 tons. The market is still easy, although some bullish brokers think low prices have been touched. A large sale of Australian from yard is reported to have been made at $6.50 a ton. Large consumers, unless offered inducements, are said to be offish about buying beyond immediate wants; indeed the most of them are reported to be well stocked.

Eastern Metal Markets.

By Telegraph.

NEW YORK, April 4, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42½	92¾	$14 75	$3 62½	$21 00
Friday	42⅝	92¾	14 50	3 65	21 05
Saturday	42½	92⅝	14 50	3 67½	21 05
Monday	42 3-16	92½	14 50	3 67½	21 10
Tuesday	42 3-16	92½	15 00	3 67½	21 15
Wednesday	42½	92⅝	14 50	3 67½	21 25

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Justice, March 29, $3900; Confidence, 29, $51,540; Crown Point, 29, $9516; Alta, 29, $30,129; Hale and Norcross, 30, $7400; Bluebird, 29, $18,816; Con. California and Virginia, 30, $75,240; Hanauer, 29, $2100; Navajo, April 3, $8000; Mt. Diablo, 4, $7830; total for March $36,348; Hanauer, 1, $2500.

Mining Share Market.

Stocks the past week were quiet, with a gradual sinking in prices, alternating with spasmodic efforts at reactions. The street is full of all kinds of rumors—all of a bearish character, while it is very hard to obtain reliable news from the mines. This condition always obtains when the pool is manipulating to get in stocks at low prices. The Crown Point Company at Virginia City only shipped in bullion last month $37,347, with the final cleanup to hear from. Potosi is shipping ore to the Nevada mill.

The following companies report having had a balance on hand April 1, 1889: Belcher, $22,024.72; Consolidated Imperial, $14,287.36; Best and Belcher, $1952.45; Lady Washington, $23,510.80; Alta, $67,131.26; Consolidated California and Virginia, $157,097.02 in cash and $75,240.94 in unsold bullion, with further shipments to arrive; Mono, $9267 97; Bodie Consolidated, $24,076.40; Occidental, $3057.76; Gould and Curry, $928.14; Hale and Norcross, $10,309.67 in available cash, and the bullion returns for March not all in; Ophir, $2310.07; Exchequer, $3350.10; Alpha, $12,660.80; Silver Hill, $5835.70; St. Louis, $3702.60; Andes, $9925.43; Syndicate, $8638.71; Found Treasure, $4.80; Crocker, $299.54; Peer, $1750.92; Locomotive, $839.03; Confidence, $79,107.14; Caledonia, $11,222.34; Overman, $19,100.83; Navajo, $27,654.12 in cash and $8000 in bullion; Independence, $1842.09; Diana, $4182.35; Standard Consolidated, $20,288.14; Silver King, $38,000; Benton Consolidated, $95,422.62; Julia, $6056.40; Bullion, $25,358.09; Scorpion, $7300. The following report an indebtedness on that date: Grand Prize, $42,767.52; Nevada Queen, $56,403.56; Commonwealth, $59,406.52; North Belle Isle, $17,373.31; North Commonwealth, $18,230.28; Del Monte, $3398.55; and Belle Isle, $4706.31.

The following companies report having had an indebtedness April 1, 1889: Crown Point, overdraft of $15,673, with bullion of the assay value of $10,294.86 in bank as a partial offset, and other shipments to come; Challenge Consolidated, $1833.28; Bulwer Consolidated, $700.74; Seg. Belcher, $14,299.28; Savage, $15,340.22; Sierra Nevada, $7934 82; Potosi, $16,812.28; Mexican, $3946.01; Chollar, $6820.65; Holmes, $3748.93; Con. New York, $3748 93; Peerless, $8330.33, with the March bullion product not yet received; Weldon, $277.03; Utah Consolidated, overdraft at bank of $4401.17.

The ore yield of the Comstock mines during the week ending March 30th aggregated 6716 tons, divided as follows; Con. California and Virginia, 2877 tons, battery sample assays showing a value of $34 90 per ton; Savage, 527 tons, assaying $22; Hale & Norcross, 817 tons, assaying $25.09; Confidence, 653 tons, assaying $31.12; Crown Point, 912 tons; Overman, 318 tons; Justice and Alta, 500 tons; Gould and Curry, 112 tons, assaying $22.12. The combined bullion yield of the above was about $150,000.

The Exchequer Mining Co., Virginia City, has levied an assessment of 25 cents per share. The Confidence Mining Co. has declared a dividend of $1 per share, and the Con. California and Virginia one of 50 cents per share.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

SEPARATIONS.—In the article on "Separations," published in the PRESS of March 30th, in the paragraph on "Copper, Nickel and Cobalt from Zinc and Cadmium," the sentence "in this sulphate solution," should read "in thiosulphate solution."

New Incorporations.

The following companies have been incorporated, and papers filed in the office of the Superior Court, Department 10, San Francisco:

SAN FRANCISCO STREET RAILWAY CO., March 28. Capital stock, $2,500,000. The lines that will be operated are as follows: From the water-front on Market street to the intersection of Pine and Central avenue, along Market, Pine to Central avenue, returning by same route. From the bay on Fillmore street to the corner of Church and Thirteenth, along Fillmore to Ridley, to Church, to Thirteenth and returning by same route. From the corner of O'Farrell and Market to Fell and Stanyan, along O'Farrell to Fillmore, to Fell, to Stanyan, to Fillmore and Pine, where the other system will connect for the ferries. The total length of all the proposed lines is 25 miles. Directors—C. O'Connor, R. P. Hastings, Fisher Ames, Thos. J. Clunie and A. E. Davis.

ELK CREEK R. R. CO., March 29. Capital stock, $500,000. The object is to construct a narrow-gauge railroad of a length estimated at 32 miles. The road will commence near the mouth of Greenwood or Donahue creek, in Mendocino county, thence by the most practicable route to Elk Creek, thence up Elk Creek to a given point of survey, thence to the main branch of Alder creek, a distance of 24 miles, constituting the main line of the road. A branch road will be built from the main line on the right branch of Alder creek and will run along the line of the creek to about three miles from its mouth, an estimated distance of eight miles. Directors—L. E. White, J. H. Tate, Charles E. Wilson, T. Pollard and E. J. Dodge.

GARFIELD G. M. CO., April 1. Location, Greenwood district, El Dorado Co. Capital stock $500,000. Directors—J. E. Scott, J. B. Curtis, P. J. White, W. A. L. Miller, Wm. W. Bishop, James A. Watt and J. H. Sayre.

NIANTIC G. M. CO., April 2. Location, Nevada Co. Capital stock, $1,000,000. Directors—Frederick H. Hansman, Walter Speyer, Alexander Hay, James H. Mundy and Frederick K. Shawhan, all of this city.

WESTERN IRON WORKS, April 2. Object, to conduct a general foundry business. Capital stock, $60,000. Directors—Willard B. Morris, Howard C. Houghton, James Campbell, Hugh Jones and William D. Noyes.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side-track of the Atlantic & Pacific Railroad. They contain a first-class 50-horse power Engine and 45-horse power Boiler with Ore Crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling house (portable). The above can be had at a bargain. Apply to GILLESPY & CHILDS, 123 California street, San Francisco.

Every Miner His Own Assayer.

A chemical for testing and ascertaining the value of all kinds of ore, by which every miner and prospector can make his own assays, anywhere in the mountains, at a cost of a little over 5 cents and in a few minutes' time. No apparatus or dangerous acid needed; a dry powder, which may be carried in the pocket. This, mixed with the ore and a little water in a teacup, produces an electric current, which separates the silver from the ore instantly, no matter how refractory. Try it; you will be delighted. Will save you many dollars for assaying. Package sufficient for 30 tests, with full directions, by mail to any address on receipt of $2; 6 packages for $10. Address, Prof. J. Herman, P. O. Box 1845, San Francisco, Cal.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

WM. H. TAYLOR, President. R. S. MOORE, Superintendent.

Risdon Iron and Locomotive Works,

MANUFACTURERS OF ALL KINDS OF

Mining and Milling Machinery, Engines and Boilers,

SHEET-IRON WATER PIPE for Mining and Irrigation Purposes.

ALSO SAWMILL MACHINERY.

Exclusive Agents for the Pacific Coast of HEINE PATENT SAFETY BOILER and MACBETH STEEL PULLEY.

AGENTS FOR THE PACIFIC COAST OF

BRYAN'S ROLLER QUARTZ MILL.

NEW COMMON SENSE STEEL WHIM.

All Complete for $150.

No cog-wheels or clutches to break. Ninety per cent of this Whim is wrought iron and steel, and will spring or bend before breaking, and besides can be repaired at any blacksmith shop, should breakage occur, thus obviating the necessity of sending away hundreds of miles sometimes, and waiting a week for repairs. The Brake sets itself when the horse stops or anything gives way.

It can be packed anywhere a jack can go, the heaviest piece weighing but 100 pounds; total weight, 650 pounds. The sweep can be thrown out or in gear at any time, and the bucket hoisted, dumped or lowered while the horse is in motion. It is just as safe and reliable as an engine, and can be handled as readily, and is just the thing to open up a mine and make it pay. Spending thousands of dollars in fine machinery and shaft houses has "busted" many a company. Buy a COMMON SENSE WHIM, and when you have got more ore than our Whim will hoist, then it is time to buy an engine, not before. It will save you thousands of dollars if your mine should not pay. Being all iron except the sweep, it will not rot, warp, twist, or get out of true. Being wrought iron, it will not break in transportation. We also make Two, Four and Eight Horse Power Whims, Derrick Whims, and Building Hoists, Ore Buckets, and everything pertaining to Horse Power Hoisting. State for what purpose, and at what place you want to use it.

☞ Come and see one at our works in operation, or send for circular.

MINERS ATTENTION!

SPRAGUE ELECTRIC RAILWAY AND MOTOR CO., OF NEW YORK.

LOW-GRADE ORES CAN BE PROFITABLY WORKED BY ELECTRIC TRANSMISSION OF POWER FROM DISTANT WATERFALLS.

Plants will, in many cases, pay for themselves in from 1 to 5 years by the saving produced by Electric Transmission compared with other systems.

Suspension and Surface Tramways, Hoists, Pumps, Drills, Stamp-mills, etc., operated by Electric Motors.

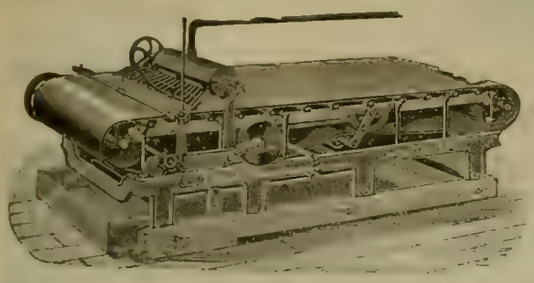
$1,000 CHALLENGE ACCEPTED,

PRICE, FIVE HUNDRED AND FIFTY DOLLARS
($550.00).



THE
"TRIUMPH" ORE CONCENTRATOR.

The present improved form of the celebrated "TRIUMPH" Ore Concentrator possesses many advantages over any other style of Vanners, Vanning Machines, or Concentrators, yet introduced to the notice of mining men. These advantages consist in the superior features which enter into their construction, and facilitate their operation.

They are constructed in the best manner; their frames being of iron, insures their solidity, durability, and perfect steadiness of motion when operated. They are built as compactly as their requisite strength will permit, weigh less, require less freight space in boxes, by which their cost of transportation is reduced, and occupy less mill room when set up.

An important improvement has recently been introduced into their construction, which consists of a RIFFLE TABLE placed in front of and which takes the discharge from the feed and amalgam bowl. The improvement is in the reciprocal motion which is imparted to this table by the longitudinal motion of the shaking frame to which the table is attached. We have at hand many testimonials, from well-known Superintendents of mines in different mining districts of the United States, bearing evidence of the efficiency and superiority of this form of Concentrator, and we shall be pleased to send Circulars covering such letters of testimony, and, as well, directions for setting up and operating these machines, and are ready to quote special prices for any considerable order.

New York Office, 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

An Illustrated Journal of Mining, Popular Science and General News.

BY DEWEY & CO. Publishers.

SAN FRANCISCO, SATURDAY, APRIL 13, 1889.

VOLUME LVIII. Number 15.

A Ledge.

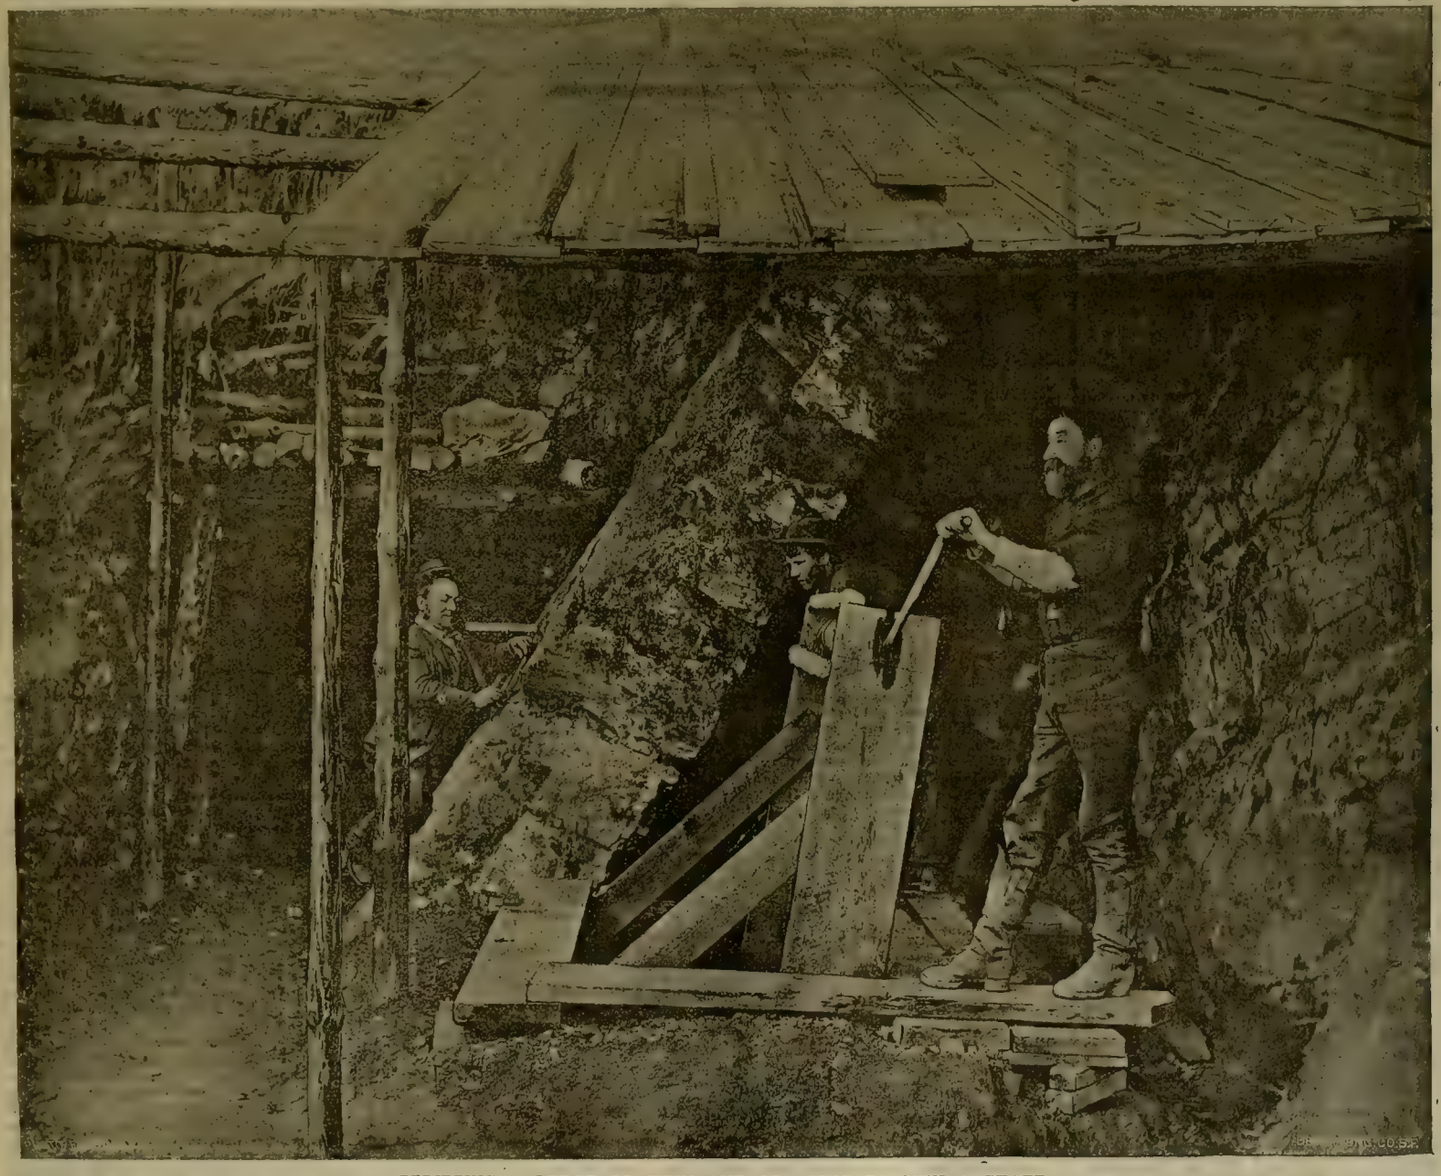
We give on this page a photo-facsimile of a ledge or vein, made from a photograph taken in the gold-mining regions of California. It shows the vein or ledge "stripped" and the men sinking a shaft. The windlass shown is the rough, common form used in the mines for preliminary work.

A mining engineer is using a clinometer to get the dip of the vein. The picture happens to be a good one of a well-known mining man and will be recognized by many.

We do not remember having seen a better illustration of a vein or ledge than that presented. The ledge has been stripped and stands out prominently, isolated from the surrounding rock. Those not familiar with mining matters can see from this how "the ledge" looks. In this vein or strip of rock is contained the ore which the men are in search of. The shaft or winze is continued down vertically, and drifts are run out to the vein and along its course, the vein being removed and taken through the drifts and shaft to the surface. Different levels are run from the shaft, and the vein is removed from all the space it occupies between the levels.

Some portions of the vein are richer than others. There may be a "chimney" of ore in the vein extending for some distance in all directions, and then a comparatively barren space may be met. The vein varies also in width occasionally. In some instances the gold is disseminated pretty evenly all through the rock of the vein, and again it comes in "pockets" or bunches. Moreover, while near the surface, the gold is found "free," or in pure native state; sometimes as depth is attained it is so combined with sulphurets that more elaborate processes are required to obtain it.

All ledges are by no means so wide and solid-looking as that shown in our picture. Ledges in gold mines vary from one to three feet, though they are occasionally much wider and sometimes narrow down to a mere "knife-blade." The very large ledges are apt to be of low grade. There are so many peculiarities to veins, however, that they could scarcely be enumerated in the course of a brief article.



STRIPPING A LEDGE OR VEIN AND STARTING TO SINK A SHAFT.

The black-sand placers on the ocean beach near Lompoc, Santa Barbara county, are causing some local excitement.

Ore in Dispute.—The Standard Consolidated M. Co., owner of the West Bullion lode in Mono county, has filed a suit in the U. S. Circuit Court against the Bulwer Consolidated Mining Co., which operates the Ralston claim adjoining, to settle the ownership of a lode which in its course runs under the surface boundaries of both claims. The plaintiff asks judgment for $2400 for ores taken out and for $5000 damages.

The first number of the new paper at the Santa Clara gold-fields, in Lower California, was issued March 23d. It is called the *Nugget*, and is a three-column sheet, printed on one side, but promises to grow if the town does.

The San Francisco Microscopical Society will give a public exhibition in August.

A Cylindrical Observatory Dome.

A Design for a Cylindrical Dome for a Thirty-Six-Inch Equatorial Telescope.

[An undergraduate thesis, by W. E. Downs, University of California.]

Astronomy is doubtless the most ancient of all sciences, dating back to the earliest records. Since the heavens could not fail of being an object of keen attention to the most primitive race, the study of the celestial bodies is as old as man himself. The recurrence of conjunctions and eclipses, the successive intervals of light and darkness, and the regular change of seasons, must have aroused a desire in earliest man to account for these phenomena by movements of the heavenly bodies, and must have led to systematic study and observations of their motions and positions. We have records of such an attempt to analyze the movements of the planets, in what is known as the Ptolemaic theory. The supporters of this theory supposed the earth to be a fixed center, around which the sun and heavenly bodies revolved by means of a system of invisible bars and cranks. By the aid of this incongruous combination, the places of the sun and planets were so accurately predicted that the error could not be detected by the rude instruments then in use.

Centuries later Lipperhey, a Dutch spectacle-maker, found, by chance, that two pieces of glass of certain shapes possessed, when rightly placed with respect to each other, the remarkable property of making distant objects appear near.

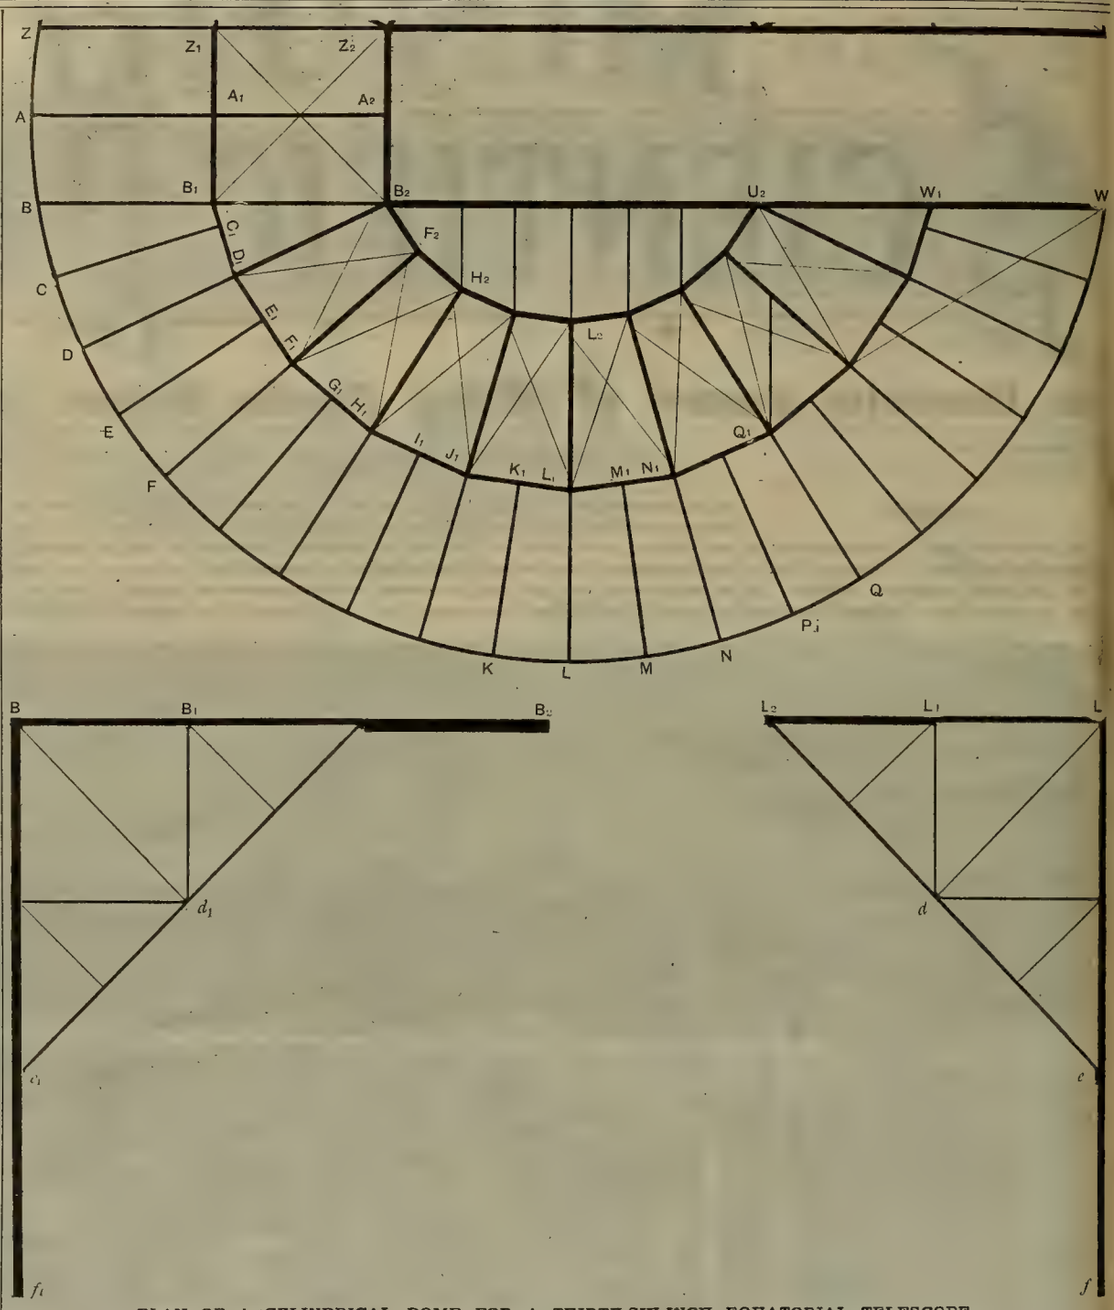
Galileo, the eminent philosopher, at once realized what possibilities such a discovery might lead to, and hastily constructed an instrument for testing its value. Though this instrument consisted simply of a lead pipe with a piece of glass set in either end, it was the first telescope, and demonstrated the practical worth of that class of instruments which was destined to overthrow the old Ptolemaic theory, to revolutionize the science of astronomy, and to furnish for it a solid foundation by revealing the secrets of the heavens. From that time to the present, the telescope with its appliances has been gradually nearing perfection, until to-day the intelligence of many distinguished scientists, aided by the mechanical skill of thoroughly trained workmen, has been enabled to produce an instrument that is of infinite value in the determination of celestial laws and conditions. The fact that the highest degree of perfection has been achieved by California, that there is now at Mt. Hamilton a telescope with bountiful equipments outranking all instruments of the kind in the world, imparts new interest, not only to astronomy, but to the means employed in the manufacture and preparation of the glass, and to the many intermediate steps in the construction necessary to place this instrument in perfect working order.

A feature that is of much interest to the writer, and which forms the subject of this paper, is the designing of a suitable dome for a 36-inch equatorial telescope. The length of the tube of the great telescope at Mt. Hamilton was calculated to be such as to require a dome of about 75 feet in diameter. Accordingly, an immense hemispherical dome was designed and constructed for that purpose. In order that the eye end of the telescope might be accessible to the observer at all times, an elevating floor of many tons weight partly counterpoised, operated by hydraulic engines, was necessary. In our designs we have chosen a cylindrical dome of rolled steel, feeling confident that the same degree of convenience could be obtained at a greatly reduced cost, both in the original construction and in subsequent operation, as is now secured by the present hemispherical form.

In place of an elevating floor and a curved shutter such as now exist in the great Lick dome, we will have an elevating platform and two shutters. The platform will be designed to carry two or three observers, together with a few necessary instruments to be used by them in working, and will be suspended from the roof just opposite the opening through which the telescope is to point. To secure ease of movement, it will be almost wholly counterpoised by four large weights. As regards the two shutters, we will designate one as the vertical and the other as the roof shutter. The former may be opened like an ordinary door and the latter will be counterpoised by a weight rolling upon a specially designed curve, and may be opened like an ordinary trap-door.

The advantages of a cylindrical shape are: first, ease of construction, since nearly all of the pieces will be straight and will have cross-sections of the ordinary commercial forms; second, (*a*) ease in operating the shutters, since they are to be controlled by the observer when he is on his platform, and, (*b*) convenience, since when observing in any portion of the heavens less than 41 or 42 degrees from the zenith or from the horizon only one shutter need be opened; third, ease with which the observer may control the movements of the platform while upon it.

The roofing of the Lick dome, as actually constructed, required a large number of special iron plates which added not a little to the cost of material, while the horizontal roof of a cylindrical dome could be easily covered with corrugated iron or iron plates similar to those now in use. The walls would require only



PLAN OF A CYLINDRICAL DOME FOR A THIRTY-SIX-INCH EQUATORIAL TELESCOPE.

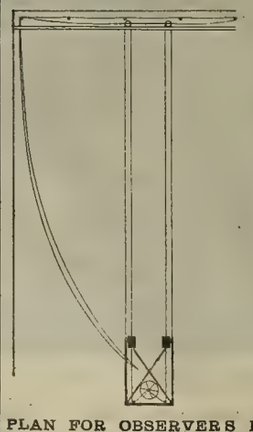
common rectangular plates curved to an arc, whose radius would be that of the cylinder.

For construction of the frame, steel is recommended in preference to wrought iron, because of its superior strength and its tendency, as now manufactured, to be of a more uniform grade.

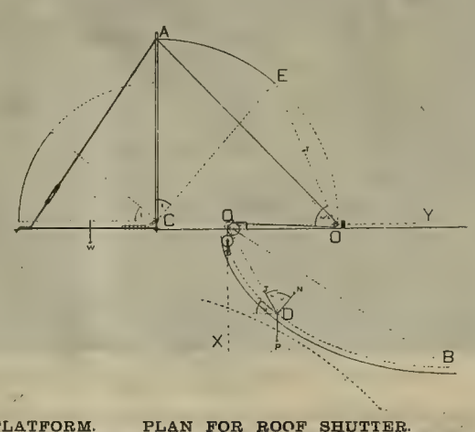
The weight of the dome would, as we have computed, be less than six-tenths of that of the Lick dome. This decrease in the weight of the material used would be an important factor in the cost of construction, especially when we consider the distance and difficulty of transportation.

In the following figure we will refer to the girder whose flanges are A_1B_1, B_1D_1, etc., and A_2B_2, B_2F_2, etc., as the circular girder.

Each flange will be made of at least three separate pieces. The center pieces of both flanges will be 12 feet long, which is the width of the shutter and a little heavier than their corresponding side pieces. The side pieces of the inner flange, which are symmetrical, will each be bent into eight equal parts, each part being the chord of a circle which is concentric with the axis of the dome. The corresponding pieces of the outer flange, which are also symmetrical,



PLAN FOR OBSERVER'S PLATFORM.



PLAN FOR ROOF SHUTTER.

will each be bent into ten parts forming chords, or parts of chords, as the case may be, of a larger concentric circle.

We have taken the mean diameter of the dome as 74 feet 3 inches, and the width of each shutter as 12 feet. This particular width of the shutters is such as to allow for an opening of from three to four times the diameter of the objective, so as to give ample room for a star to remain in the field of view for a reasonable length of time without the necessity of revolving the dome. We have taken the hight of the moving part of the dome as two feet greater than its radius, so as to give room for the curve that holds the counterpoise weight of the roof shutter, and for the counterpoise weights of the observer's platform. The dimensions of the various members of the dome have been computed analytically.

In calculating the strains resulting from the horizontal wind-pressure, the maximum pressure has been assumed to be 50 pounds per square foot of surface, which corresponds to a wind velocity of about 100 miles an hour.

We have assumed the pressure on the roof due to the weight of construction as 18 pounds per square foot, and have calculated upon a snow-pressure of 20 pounds, which would be a proper estimate for California climate, and a vertical wind-pressure, which is small in cases of this kind, of two pounds per square foot. The total vertical pressure would therefore be 40 pounds per square foot.

After taking into account the additional tension and compression strains due to these causes that come upon the circular girder, it was found that the strains for horizontal wind-pressure, if multiplied by 1.4, would give sufficiently accurate results for maximum strains. Since the stresses are computed for very high wind-pressures, with a somewhat large safety factor, and as the weight of the observer's platform is small so that it may be easily operated, we need compute no further. The allowable stress will be made 20,000 pounds per square inch.

All except the interior members of the dome have been dimensioned to resist bending moments due to the wind-pressure and the weight of construction and snow, in addition to resisting the forces already considered. In dimensioning, the Union Iron Mills catalogue has been used as a basis of calculation.

In order to brace Bf_1, Wf_1, etc., and Cf, Df, etc., we will have two continuous angle bars which will be bent into lengths equal to CE, DF, etc., and which will go around the structure from one side of the opening to the other, at the hight e. They will resist both the inner

and outer horizontal forces coming upon the vertical struts Bf_1, Cf, etc., at e_1, and e.

The elevating observer's platform will be 5x5 by 7 feet high. It will be suspended from pulleys that are attached to a car or truck. It will be counterpoised by four large weights, two of which are shown in the drawing. The weight of the empty platform will be slightly greater than these four weights so as to prevent its rising alone. The track upon which the car is to run will be rigidly fastened to the eyebars ZZ_1Z_2, AA_1A_2, and BB_1B_2 (see large figure), and 18 inches below them. It will consist of two rails gauged 4 feet 6 inches apart. The pulleys will be fitted upon the extension of the axle; that is, just outside of the wheels, so as to permit of lateral bracing between the rails.

The reason for having the platform rather high, as it appears in the drawing, is to make the center of gravity as far as possible below the points of support so as to prevent unsteadiness. Small weights of say 15 or 20 pounds, in friction slides fastened to the wall of the dome and connected with the observer's platform by ropes, would tend to prevent swinging.

The platform with its attachments may, however, be designed and constructed after everything else is completed, so as to suit the observer.

The vertical shutter will be 39 feet 1½ inches high. It will be securely hinged to the vertical strut running from W down to the upper track. There will be two ropes attached to the lower end of this shutter—one to open and the other to close it. They will run around either side of the dome to the observer's platform. In order to prevent any shock, a set of springs will be fixed to the dome, so as to receive the shutter when opened.

The roof shutter will be 49½ feet long. The drawing shows the manner in which it is hinged and counterpoised. When closed, the center of gravity of the shutter and its rigid appendages are at the same hight as the hinge. The curve is so designed that the weight rolling upon it will be in equilibrium with the shutter, for, suppose the shutter to be half or two-thirds open, then the tension in the rope leading from it to the weight will be such that both will remain where they are if left undisturbed.

Since friction acts both ways, we have disregarded it in the calculation of this curve, but in the designing of the details we will make the parts as frictionless as possible.

$O_1D - r$ = radius vector of the curve when O_1 is the pole.

l = length of rope less $OO_1 = EO + O_1D = AO - BO_1$.

P counterpoise weight on the curve.

T = tension in the rope.

W — weight of the shutter and its rigid appendages.

N = normal pressure exerted by the curve upon the weight P.

a distance from C to the center of gravity of the shutter and appendages.

b $CO - CA$

t, u, v and w represent angles.

The moment of force about C due to either W or $T = Wa\cos t = Tb\sin w$ but $\sin w = \frac{b\cos t}{l-r}$ $\therefore$ $Wa = \frac{Tb^2}{l-r}$

$\therefore$ (1) $T = \frac{Wa(l-r)}{b^2}$

$T\cos u + N\cos v = P$ and $T\sin u = N\sin v$

$\therefore$ (2) $T(\cos u + \sin u \operatorname{ctn} v) = P$ whence

(3) $\frac{P}{Wa}\frac{b^2}{} = (\cos u + \sin u \operatorname{ctn} v)(l-r)$

For $u = 0$, $v = 90°$ and $r = 0$

(4) $\frac{P}{Wa}\frac{b^2}{} = l$ which shows, as a necessary consequence, that P depends upon W when the values of the constants a, b, and l are given. From (3) and (4) we have:

(5) $l = (\cos u + \sin u \operatorname{ctn} v)(l - r)$ where

$\operatorname{ctn} v = \frac{dy}{dx}$ and $\begin{cases} x = r\cos u \\ y = r\sin u \end{cases}$

multiply (5) through by r, then —

$lr = (r\cos u + r\sin u \operatorname{ctn} v)(l-r)$

$\left\{ x + y\frac{dy}{dx} \right\}(l-r) - \frac{1}{2}\frac{d(x^2+y^2)}{dx}(l-r)$

$- \frac{1}{2}\frac{d(r^2)}{dx}(l-r)$

$\therefore$ $2ldx = \frac{l-r}{r}d(r^2) - d(2lr - r^2)$

By integrating, we have,

(6) $2lx = 2lr - r^2 + [c = 0]$ or

(7) $2lr\cos u = 2lr - r^2$, the polar equation of the curve. This may be thrown into the form,

(8) $r = 4l\sin^2\frac{u}{2}$

the inverse of a parabola with respect to the focus which is called a cardioid.

The following table gives a few values of x and y corresponding to given values of r (in feet), from which the inner curve has been drawn:

r	x	y	r	x	y	r	x	y
1	98	.21	8	6 55	4.60	16	10.18	12.34
2	1 91	.60	10	7 73	6 35	18	10 64	14 52
4	3.64	1.67	12	8 73	8 24	20	10 91	16 76
6	5 18	3.02	14	9.55	10.24	22	11.00	19.05

From this curve distances equal to the radius of the roller P were laid off and the new outer curve, the one that P actually rolls on, was constructed. The curve that is shown in the drawing just below these two represents the edge or surface of the hemisphere that the dome is supposed to circumscribe.

We have made that part of the rope OO_1 inclined, to guard against water running along it into the dome, and have covered the pulley where it enters the dome. The covering will be just low enough to be cleared by the vertical appendage of the roof shutter when the latter is lowered.

In opening and closing the roof shutter ease of operation and perfect freedom from all shocks or jars may be secured. To prevent shock in opening, a spring will be placed just back of the pulley at O, and in closing several springs will be properly fixed to the dome on the left hand side of the opening as we look out.

The movements of the roof shutter, as was the case with the vertical one, may be completely controlled by the proper arrangement of ropes fastened to the inner end from the observer's platform.

Both shutters will have some sort of trap-door attachments—which will be controlled from the observer's platform—to keep them in place when not in use. They will be made perfectly water-tight.

The area of the top and sides of the dome is 13,457 square feet. For roofing to cover this area we have taken galvanized corrugated iron, Birmingham wire gauge, No. 24, the thickness of which is given in Trautwine as 0 022 of an inch. Its weight is 1.44 pounds per square foot of roof. The total weight of this kind of roofing for the dome is 19,378 pounds.

The weight of the observer's platform, the roof shutter with its appendages, the attached curve with the counterpoise weight, and some smaller pieces not included in the general calculation of the frame will not, at the very highest estimate, exceed 10,000 pounds. Adding this to the weight of the frame and roofing, which is 94,577 pounds, we have for the total weight of the structure 104,577 pounds, or about 52 3 tons, which is a little more than half the weight of the great Lick dome. This estimate may be reduced to about 46 tons, by designing the vertical struts Lf, etc., with less metal area, but with the same moment of resistance as they now have.

The dome will be revolved by water-power, as is the case of the Lick dome, and controlled from the observer's platform through a system of ropes. We have heard it stated by good authority that the great telescope will be controlled by an observer at the eye end of the instrument. Thus we see that everything about our dome, together with the telescope, may be controlled from the observer's platform.

We feel convinced that the design proposed would be far cheaper than the present great dome, fully as substantial, and much more suitable.

To the Editor of the Mining and Scientific Press—SIR: In presenting this thesis to you for publication, allow me to make a few remarks with suggestions that have come to my notice since its completion last June.

Its character and scope is illustrative of what is required of a civil engineering student just prior to graduation. It is, like all others of its class, written with but very limited experience on the part of the writer as a foundation to work from and is only the first draft. In the copy that I send you I have reduced and omitted many of the tedious mathematical calculations and tables, but have strictly adhered to the principles set forth in the original.

Several changes may be made in the original design. 1. In addition to the regular camber, the roof should be slightly inclined from the edge up toward the center—just enough to insure rapid and thorough drainage. 2. The pressure on the roof due to the weight of construction was originally assumed as 18 lbs. per square foot, but by taking the actual figures for the weight as computed in the first draft it becomes 12.6 lbs. Now since the weight of construction would be less under a reduced pressure we can safely take the weight per square foot as 12 lbs. and consequently the total pressure as 34 lbs. per square foot. 3. The pieces BB_1, etc., B_1B_2, etc., LL_1, etc., and L_1L_2, etc., should each be braced at one point at least, say their centers, by small braces running from d, etc., and d_1, etc. Such a system would save considerable material and lessen the weight of the dome. 4. A system of ties or braces running from the d under L_1 to J_1 and N_1, etc., would give rigidity to the structure. 5. The hight of the dome may be lessened by a few inches so that the curve for the counterpoise weight of the roof shutter will be tangent to the hemisphere that the dome is supposed to circumscribe. This will not interfere with the movement of the observer's platform nor materially reduce the space for interior bracing. The hight could be made equal to the radius of the dome and the curve fitted in afterward, but in our case we do not think it is best to do so. 6. For very *exact* and prolonged observations, it is necessary that the astronomer should have as comfortable a position as possible. To insure this, many devices have been used. When a large refracting equatorial telescope is kept for any length of time on one object, the eye-piece moves quite rapidly, making frequent changes of the observer's position necessary. In our case it would require but little skill to devise some means of obviating this difficulty. The power that moves the dome may be made to act continuously during observation; in which case shutters of much less width than those shown in the design could be used. This motion may be regulated by the observer so that he will always have the right position in azimuth. The horizontal (radial) and vertical motions of the platform relatively to the dome may also be made continuous and completely under the observer's control.

W. E. DOWNS.

Mohave County, Arizona.

EDITORS PRESS:—The mines of Mohave county are beginning to be looked upon by mining men as the richest silver producers in the Territory, and they are deserving of far more attention from mining capitalists than they have received.

The Cupel mine, owned by Spruance, Stanley & Co., San Francisco, with an expenditure of about $25,000, produced or netted the lessee, J. K. Mackenzie, over $100,000 the past year.

The C. O. D. mine, owned by a Mr. Drexler of San Francisco, has been a steady paying property for the past four years. The Prince George South, owned by the same party, paid nearly $100,000 on an investment of $15,000.

The Prince George North, leased to J. K. Mackenzie, is producing an immense quantity of ore, ranging in value from 150 to 200 ounces silver per ton. On the face of the north drift, on the 60 foot level, there is six feet of solid ore of the above grade.

The Nighthawk, owned by Geo. Bowers and Sarah Althea Terry, has produced a good deal of high-grade ore during the past year, and is again to the front looking better than ever.

All the above mines are located in the vicinity of Stockton Hill, one of the richest silver camps in Arizona.

The Flores mine and mill at Cerbat is running night and day on good grade gold ore. The superintendent, J. H. Campbell, has been laboring under difficulties ever since his appointment to the superintendency, but has surmounted them, one by one, and now has everything running along as smoothly and successfully as could be desired.

The mill of the Arizona Northern Co. at Cerbat is being repaired, and will be started upon custom ore in a few weeks.

It is rumored that the Copper World mine near Yucca, has been sold, but the price has not been stated. The World is the highest grade copper mine in this section of Arizona.

The Rattan mine in San Francisco district, recently sold to a St. Louis company, is having a steam hoist put up and will soon erect a ten-stamp mill near the mine. The ledge is about three feet in width and carries about two ounces gold per ton.

The Old Moss, or Montezuma mine, as it is now called, has been sold to a New York company for $60,000. The company will erect a large mill on the Colorado river, nine miles from the mine, for the reduction of ore.

Altogether the mining outlook for 1889 in this county is good. JO KING.

A GERMAN MODE OF BRONZING.—A German technical journal gives the following method of producing a bronzelike surface on iron or steel, which prevents rust: The object to be acted upon must be cleaned so as to take off all oxidation or other impurity. It is then exposed for two or three minutes to the action of the vapors of the heated mixture of hydrochloric acid and nitric acid in equal portions, at a temperature ranging from 550° to 650° F. After the objects have cooled, they are to be rubbed over with vaseline and again heated until the vaseline begins to decompose. This treatment with the vaseline has to be repeated once. Should a lighter coloring than bronze be desired, it can be produced by mixing acetic acid with the other acids.

A VEIN of mineral soap was discovered last week in the bluffs north of the Italian ranch, about 15 miles east of the Comstock. An analysis disclosed the presence of a large percentage of arsenic in the composition. The vein is 18 inches in width. The color of the deposit is a light gray and contains but little grit. In its natural state it produces a lather equal to that of the finest soap used by barbers.

FAMOUS NUGGETS.—The famous "Welcome nugget" was worth $43,900. The "Welcome Stranger nugget," the largest ever found in the world, was worth $57,280. These figures are from official reports of the Melbourne Government.

THE profits of the Sutro Tunnel Co. since 1883 foot up more than three-fourths of a million. The receipts for royalty during January, 1889, were $22,200. The daily receipts for royalty on ore being extracted average $950.

SOME men in New York has produced an imitation gold which it is said defies the usual tests. Buyers of bullion may as well be on their guard.

Notes on Leaching Silver Ores.

NUMBER 2.

[Written for the MINING AND SCIENTIFIC PRESS by C. H. AARON.]

After many experiments with the Stetefeldt and the "Modified Howell" furnace, some "double-hearth" reverberatory furnaces were built, the lower hearths having 220 square feet of area and the upper 210 feet each, so that it seems they were really two-storied, two-hearth furnaces. "Each double furnace took four charges of one ton each. When one charge was finished all the others were moved forward, and on the first hearth a new charge dropped through an opening in the arch. From the second hearth the charge was dropped on the lower hearth through an opening in the bottom near the working door. The upper hearths were exclusively used for oxidizing roasting and the four per cent of salt were added while the charge was dropped on the lower hearth. * * Each charge was 10 to 12 hours in the furnace." The results were similar to those of the modified Howell furnace.

A series of interesting experiments were made in these furnaces, for the details of which I must refer the reader to the original articles. The consumption of wood in these furnaces was one cord to nine tons of ore.

"Both furnaces, the modified Howell and the reverberatory, gave about the same results, and the loss by volatilization was also nearly the same. The cost of roasting, however, is very different. We find the cost per ton of ore in the modified Howell to be $4.50 and in the reverberatory $3.67."

This will be a surprise to some; it results mainly from the low price of labor in Mexico, as will be seen by the following estimates from Mr. Hofmann's paper:

COST OF ROASTING 8½ TONS PER DAY IN THE MODIFIED HOWELL FURNACE.

2 head roasters at $1.60	$ 3 00
4 helpers at 90c	3 60
4 per cent salt, 680 pounds at 1 27c	8 63
15.7 cargas of wood at 75c	11 77
Steam-power, 10 cargas of wood at 75c	7 50
Oil, light, tools, etc	2 00
Management, office, mechanic, assay office	1 78
Total	$38 28

Cost per ton $4.50 Mexican currency.

The following is the statement of cost for two double-hearth furnaces roasting 18 tons per day:

2 head roasters at $1.50	$ 3 00
16 roasters at $1	16 00
2 wood-carriers and ore-wheelers at 90c	1 80
2 carmen for raw ore, chargers, at 90c	1 80
23.4 cargas wood at 75c	17 55
4 per cent salt, 1440 pounds at 1.27c	18 28
Tools, etc	4 00
Management, office, mechanics, assays	3 77
Total	$66 20

Or cost per ton $3 67 Mexican currency.

Difference in favor of reverberatory furnace 83 cents per ton.

This illustrates the truth of a remark which I have often made: in a country where labor is cheap, the use of labor-saving machinery is not always economical, especially if freights are high and repairs costly or difficult. Still, to quote Mr. Hofmann again: "There are, besides the merits of the furnace, other circumstances to be taken into consideration. The reverberatory furnace requires quite a number of skilled hands, and the result depends much more on the good-will and skill of the men than with the modified Howell." Mexicans, if properly handled, are, as a rule, very good workers, notwithstanding that they receive such moderate wages, but they like to lay off on Sundays and feast days. On such days quite a number of inexperienced substitutes will be found working at the furnaces, and consequently, Sunday roastings have to suffer. * * * For this reason it may be more advisable in a large mill to use the modified Howell furnace, notwithstanding that the reverberatory works cheaper and creates much less flue dust. The Howell forms a great deal of flue dust, which is far from being roasted, even if provided with an auxiliary fire."

I think it would be worth the while of those having to treat such ores as this to pay some attention to the Thompson furnace, another modification of the White, and much superior to the Howell-White. This furnace can be had with two cylinders, one for oxidizing and one for chloridizing, the former discharging into the latter. The inclination of the cylinder, and, therefore, the time of transit of the ore, is adjustable, as is also the speed of rotation which controls the exposure of the ore by showering; the air which enters the cylinder can be heated, if required, by the waste heat of the furnace and of the cooling ore. A special feature of this furnace is that the dust settling in the chamber is automatically brought to the lower end of the cylinder, and is there fed into the furnace, the greater part of it remaining with the chloridizing ore, and doing away with the need of an auxiliary fire.

In Mr. Hofmann's case it seems probable from his results in the Stetefeldt furnace, and from the description of the ore, that the greater part of the pyrite passes to the dust-chamber of the Howell furnace, and the benefit of this best of all chloridizing agents is lost to the main body of the ore. In the Thompson furnace this pyritous dust would be put exactly where it would do the most good. If the reverberatory attachment could be dispensed with by means of the two cylinders, it is probable that the cost of roasting would be even less per ton than in the reverberatory furnace.

Passing Events.

The reported discovery of silver ores in San Bernardino county is attracting some attention. The district is a distinct one from Calico, and is described in our "mining summary" on another page.

Tin, or indication of tin ore, has been found east of Duarte, in the Van Tassel canyon, Los Angeles county. The San Bernardino county deposit of tin ore has long been known and this new discovery may lead to more active prospecting for this metal throughout the mountains in the southern part of the State.

The project to make a seaport of San Jose, now being discussed, will necessitate, if carried out, very important and expensive engineering work. The plan is perfectly feasible, the only question being the amount of expense involved.

There is no news of special interest from the Lower California placers. Great numbers of those who went there during the excitement have returned, greatly disappointed. Others are still there prospecting. Some pretty good quartz claims were found, but at their present stage give no employment to labor. The whole thing was a grand "fizzle," and those who went are very bitter on the people who got up the affair and the newspapers that encouraged it.

Four Hundred Thousand Patents.

This month the patents issued by the United States are numbered 400,000 and upward.

The mere mention of the number of inventions should call the attention of people to the work that is being done by the inventive genius of the country. Patent No. 300,000 was issued in June, 1884, and Patent No. 400,000 in March, 1889. The increase of inventions in late years has been immense. It took from 1790 to 1870 to get the number 100,000 in the United States series—about 80 years—while it took less than five years to complete the last 100,000.

Among all these patents are many hundred secured by Pacific Coast inventors, mainly obtained through the agency connected with this office. Our files contain a pretty complete record of the progress of invention on this coast, all inventions of note having been described. In 1883, 765 patents were issued to Pacific Coast inventors; in 1884 there were 635; in 1885 there were 681; in 1886, 655; in 1887, 635; and last year 572.

California inventors have originated and devised many very important things aside from devices of minor importance. The insertible saw-tooth of N. W. Spaulding revolutionized the making of circular saws. The water-wheels of Knight and of Pelton have attained an efficiency which has made them known everywhere. The cable-road inventions of Hallidie, Epplesheimer, Root, Casebolt, Grim & Low, Hovey and others have made possible the magnificently rapid and efficient street-railroad systems of this and other cities. In harvesting machinery the improvements of Houser, Matteson & Williamson, the Shippee Co., Holt Bros., Best, Moore and others have almost entirely stopped the importation of Eastern thrashing machinery, and furnish in a compact form of machine by which the grain is cut, thrashed, separated, reclaimed and sacked in complete marketable condition, at a single operation in the field. The employment of steam to propel this class of machinery has received great impetus from the inventions of G. W. Berry of Visalia, who for the past few seasons has been successfully operating not only these machines in their season, but huge gangs of steam plows.

Mr. Best's inventions in grain-cleaning machinery are known all over the coast since 1871. The system of gang-plows originated here, and is still known as the "Stockton Gang."

In mining machinery we have many inventors. The pans of Wheeler, Knox, Varney and Randall; the ore-crushers or pulverizers of Dodge, Huntington, Kendall, Tustin, Stiles; the concentrators of Hendy, Morse, Adams & Carter; the ore-feeders of Stanford, Tulloch, Hendy; the silver-plated amalgamating plates of Dennison; the hydraulic nozzles of Craig, Hoskins and Fisher; Cranston's hydraulic elevator; the engines and steam machinery of Stevens, Scott, Eckart, O'Neill, Cross, Pitchford, Ohmen and Richards; the pumps of Hooker, Wilcox, Dow, Dickie, Moore and Jackson; quicksilver furnaces and condensers of Knox, Osborne, White and Randol; the ore furnaces of Stetefeldt, Bruckner, Thompson and Rueger—all these and many others are of great importance and value. The whole system of hydraulic mining with its appliances was devised in California. There have been great numbers of metallurgical processes also invented here.

The hay-baling presses, fruit-drying machines, cultivators, separators, vineyard plows, etc., are numerous. In sawmill and wood-working machinery Huntington, Spaulding, Campbell (of Parke & Lacy), Bowen (with Tatum & Bowen), Cook (with Gregory & Co.), and Robb, have made valuable and important inventions. E. L. Ransome and H. G. Fiske in artificial stone-work; P. H. Jackson in illuminating tiles, basement extensions, etc.; Forderer in skylight work; Arnold's riveting machine for leather work; dredging machinery of Angell, Von Schmidt and Bowers; Williams' water-jacket furnace; cartridge-loading machinery by Prentiss Selby; explosive compounds by Judson, Hardy and Dean; fruit packages of Swan, Morey and Weston; fruit-pitting and hulling machines by Heald, Donatelli and Alison; agricultural boilers of Heald, Enwright and Rice; Byron Jackson's thrashing feeders and straw-stacking machinery; ice machinery of Bath, Kitton, Boyle and Allegretti; logging locomotives of Dolbeer & Carson; looms of Hunt, Morris and Wilcomb; magazine guns of Snyder, Carr and Finch; road locomotives of Doane, Remington and Price—all these come to mind in thinking of important California inventions.

In writing these paragraphs many names have been omitted, as it would be impossible, without considerable research, to make a complete list of important California inventions. We write from memory only. Most of the things devised here have been called out by our necessities and the peculiar conditions of our industrial occupations. Machinery made for the purpose elsewhere did not answer the changed conditions in California, so something newer and better was demanded, and the demand was met.

Iron, Steel and Coke.

It is stated by those in position to know that the Puget Sound Iron Works at Irondale, Washington Territory, will increase their capital stock, which is now $1,000,000, with the view of erecting rolling-mills, to engage in the manufacture of steel and wrought iron in connection with their output of pig iron. The company in its various departments now give employment to about 400 men, but with the manufacture of steel and wrought iron they will keep about 100 more busy.

The Parrott Copper Company, of Butte, Montana, and the Oregon Iron and Steel Works at Oswego, Oregon, buy about all the coke manufactured by the Tacoma Coal Company, at their mines at Wilkeson, Washington. Owing to the large and growing consumptive demand the company will put in more ovens, so as to increase the output, which at present is about 100 tons a day.

TWO "HAMMONDS."—Inquiries have been made here as to whether certain reports by J. B. Hammond on mines, offered for sale, were by the well-known mining engineer of this State, John Hays Hammond. For general information, we may state that the mines favorably reported on by the latter gentleman have been bought and are being worked. No mines are being offered for sale by Mr. John Hays Hammond, and none of his reports are being used to sell mines. The similarity of names has caused the inquiries to be made.

AMONG the bills which the Controller considers inoperative is that appointing a commission to examine the rivers, the bill appropriating $350,000 for an insane asylum in Southern California, the Mining Bureau appropriation bill, and several others, making about $1,000,000 which the Controller will retain unless ordered to pay the money by the Supreme Court.

THE NEW COMET.—An approximate orbit of the comet discovered on March 31st by Mr. Barnard of the Lick Observatory has been computed by Prof. Schaebele. It is probable that this comet will become 7000 or 8000 times as bright as at present, with a distance from the sun of about 4,000,000 miles. On May 26th next it should be carefully observed.

BY an explosion at the California Powder Works, Pinole, Contra Costa county, one man was killed and another injured. Most of the men were away from the works at lunch at the time the nitro-glycerine exploded.

ASTRONOMER TODD of Amherst College has notified C. W. Irish of Carson City that the negatives of the late solar eclipse taken by him are the best that have been received from any observer.

AN OBSERVATORY DOME.—The article on pages 260 and 261 was written by a student in the Department of Civil Engineering and Astronomy of the University of California.

GEO. F. ALLEN of Petaluma has invented a "hydraulic water elevator," which he will soon put to a practical test. It is said to involve some new principles in raising water.

THE attempt to get up a gold excitement at Monrovia, Los Angeles county, met with utter failure. The largest nugget only weighed 30 cents.

MICHEL EUGENE CHEVREUL, the distinguished French chemist, has just died at the age of 102 years.

THE last cleanup of the Great Eastern quicksilver mine was 44 flasks.

H. D. RANLETT has returned to San Francisco from a trip East.

The Mining Bureau Appropriation.

The amended bill appropriating $100,000 for the State Mining Bureau, passed both branches of the Legislature, and was signed by the Governor. The measure as passed is as follows:

SECTION 1. The sum of $100,000 is hereby appropriated for the support and maintenance of the Mining Bureau, created under an Act entitled "An Act to provide for the establishment and maintenance of a Mining Bureau," approved April 16, 1880, and the Act supplementary thereto, approved March 21, 1885; and at least 70 per cent of this appropriation shall be used for geological work in the field.

SEC. 2. Not more than one-half of the said sum appropriated under this Act shall be expended during the forty-first fiscal year.

SEC. 3. This Act shall take effect immediately.

It is now stated that the bill is defective, in that it is not stated what fund the money is appropriated from. The usual and necessary form of drawing up a bill is: "The sum of $—— is hereby appropriated out of any money in the State Treasury not otherwise appropriated," etc., but in the State Mining Bureau bill there is nothing which says that the money is to be derived from the State Treasury at all.

Another defect lies in the fact that there is no clause authorizing the Controller to draw his warrant.

In view of these facts the Controller, referring to this and other bills in the same condition, says: "My opinion is that no legal appropriations were made in these bills, and unless I am ordered to by a mandamus from the court of proper authority I shall not pay out either sum. As Controller, I have no opinion to express as to the intention of the Legislature or as to the need of the appropriations. But I can't pay any money out of the State Treasury unless I am ordered to do so by the proper authority."

The officials of the State Mining Bureau do not seem to worry about the matter. The opinions of leading attorneys have been asked, and most of them think that the Supreme Court will decide that the Controller must pay the warrants if the question is brought up. Even if the appropriation proves unavailable on July 1st, the beginning of the next fiscal year, deficiency bills will probably be presented to the next Legislature to pay the expenses of the intervening two years.

There is no doubt that the Legislature intended to appropriate the money in question, and it is greatly to be regretted that any difficulty is liable to arise in obtaining it for the purposes specified. For many years the Mining Bureau was kept short of funds and little field-work was done. The previous Legislature gave it $30,000 a year for two years, and with this money State Mineralogist Irelan has been able to bring the Bureau to a point of usefulness not before attained. The information gathered by the field assistants is of a character which is needed, and which was not before available in permanent form. With the increased amount appropriated this year, and the experience already gained in field-work, very valuable and exact information relative to the mining industry of the State can be prepared. It is not gold mining alone that is benefited, but we need knowledge concerning our coal, iron, asphaltum, fertilizers, petroleum, natural gas, chrome, manganese, quicksilver, lime, borax, lead, mineral paints, copper and dozens of other things.

Mining has done much for the State, but the State has done very little for mining. The appropriation is none too large to be employed in the direction provided for in the law. Mr. Irelan has succeeded in making the Bureau more popular than it had previously been and better known to the mining community, he or his assistants having personally visited the various mines of the State in search of information. He is earnest in his endeavors to make the Bureau thoroughly useful to the mining community and to the public. It is greatly to be regretted that there should be any "hitch" in the matter of the appropriation. The trustees, Messrs. George Hearst, W. S. Keyes, Geo. W. Grayson, J. Z. Davis and Sol. Heydenfeldt, Jr., take an active interest in the affairs of the Bureau and desire to see it maintained at the point where it will be of the greatest practical value to the interests to which it is devoted.

THE Ventura *Democrat* says: It is reported that an 80-barrel oil well has recently been struck on the Cayugas ranch beyond Springville.

John Bright.

No Englishman of the present generation has carried with him to the grave such universal respect as the man whose name stands at the head of this article. From the Queen on her throne to the humblest of her subjects, the people of England have vied with each other in doing honor to the dead statesman. There has probably not been a political party during the fifty years of his active life which he has not at one time or another opposed, and sometimes with such vigor and success as to lead to its overthrow; and yet so exalted was his patriotism, and so pure the motives which prompted his opposition, that the acknowledged leader of each one of them contributed a wreath to adorn his bier and a eulogy to perpetuate his fame. Lord Salisbury, the present premier, and the embodiment of aristocratic English Toryism, against which the entire life of the great Commoner was in bitter antagonism, in his eulogy said: "He was the greatest master of English oratory in the present generation. He was inspired with pure patriotism from the beginning of his career to the close."

While he took an active part in every important measure that came before Parliament during his long political career, he was more especially identified with the repeal of the Corn laws, free trade and the extension of the suffrage. His position and arguments on each one of these questions he has lived to see triumphantly vindicated. The Corn laws were especially oppressive to the poor, who regarded him and his great colleague, Richard Cobden, as their champions, and their final repeal was made an occasion for universal rejoicing throughout England, "Cobden and Bright" being a conjunction of names embodying all that was politically hoped for by the millions of the disfranchised of Great Britain. It was the writer's privilege some time after the repeal of the Corn laws to be in the house of the great reformer at Cronkeyshaw, Rochdale, and he remembers well that occupying one entire side of the spacious library was a magnificent bookcase of English oak, embellished with carvings in relief of wheat, corn and other cereals, emblematic of the "staff of life," the gift of admiring friends in grateful remembrance of his exertions for the repeal of the obnoxious laws.

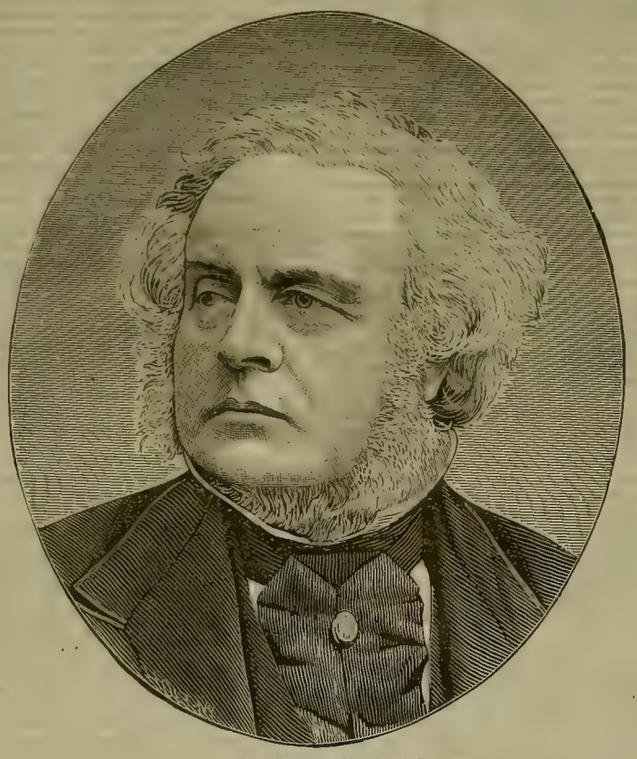
Whatever may be thought of free trade, as the policy best adapted to America, John Bright was convinced that it was the best thing for England 40 years ago, and, mainly through his exertions, laws were passed making it the settled policy for that country, and a long series of years of industrial prosperity seemed to verify the position he assumed on this question.

In regard to the extension of the franchise, if he was not so radical as some of his colleagues, he was probably wiser, his aim being to obtain, if not the best possible, at least the best he could get, and such a measure as would be best adapted to the condition of those it was intended to benefit. In this, also, he saw the fruition of his hopes and labors.

Being by birth, education and conviction, a member of the Society of Friends, his life was one long protest against war and bloodshed, and as he deemed it his duty on all suitable occasions to give emphatic expression to his convictions, it may well be imagined that he was often in hopeless conflict with the belligerent majority of his countrymen. This was particularly the case during the Crimean war between Russia on one side and Great Britain, Turkey, France and Italy on the other. His philippics, if the term in favor of peace be admissible, in the House of Commons, at this time, were among his grandest oratorical efforts, and though he knew they were entirely unavailing, and sometimes subjected him to ridicule, such was his fidelity to conviction that he was willing to brave it all rather than shirk his duty by cowardly silence. It was during one of these debates that Lord Palmerston flippantly alluded to him as "My honorable and *reverend* friend." He was promptly called to order by a friend of the sturdy Quaker, who, in the course of a scathing rebuke, told the noble lord that it ill became the representative of an insignificant pocket borough to insult the chosen representative of one of the largest industrial constituencies in England.

It seems an anomaly to American readers that a man so richly endowed and wielding such great influence should have been content for 45 years to sit in the lower house as an ordinary Commoner, and that when the party representing his ideas came into power, Gladstone, his warm personal friend and political chief, should have to labor with him half through the night to take a cabinet position in his Government, and his character can only be truly appreciated as we concede to him a lofty patriotism and a sturdy independence, which left him free to criticise or support his friends as he should be convinced their policy was for the good or otherwise of the country.

When Daniel Webster died some English



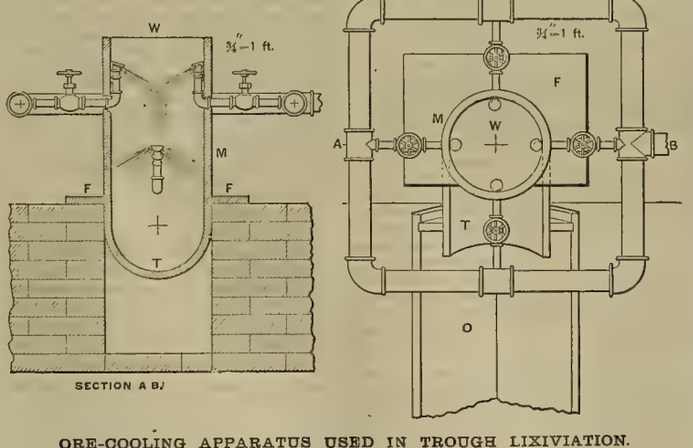
THE LATE JOHN BRIGHT.

newspapers put on the emblems of mourning in token of grief for the loss, not of a great American only, but also for the loss of a great representative of the Anglo-Saxon race, and it is meet that we testify to our sorrow, not only that England and the world has lost a great and upright statesman, but that in the death of John Bright America has lost her greatest friend when friends were needed most. Westminster may refuse his body burial, but his memory will be enshrined in the hearts of the millions the world around by whom his praises will be sung in the language he spoke so well.

Quicksilver.—The receipts of quicksilver at San Francisco in March were 1515 flasks and for the first quarter of the year 4183 flasks, against 7148 flasks last year and 6588 flasks in 1887. The exports for March were 1106 flasks, including 430 to New York and 675 to Mexico. It will be seen that the article has been very dull thus far this year. There is no demand from China, that market getting its supplies from London. Practically the only foreign demand is from Mexico.

An Ore-Cooling Apparatus.

In trough lixiviation, the transportation of the roasted ore to the settling tanks is effected by a stream of water, and it is apparent that by dropping the hot ore into the stream the costly and annoying cooling-floor manipulations can be avoided. For this purpose Mr. Ottokar Hofmann has constructed an apparatus which is shown in the accompanying cuts. It consists of a cast-iron tube *M* with a flange or plate *F* to keep it in an erect position. The lower part of the tube has the shape of a trough *T*, and is connected with trough *O*, which leads to the grinding machine. Inside the tube, and on two different levels, water spouts are so arranged and constructed that the entering water forms sheets (not sprays) which perfectly close the tube. At the line where the two opposite sheets meet, the water will drop straight down. The sheets of water are produced by placing a smooth plate of iron properly over the obliquely-cut ends of the pipes, as shown in the figure. The water-pipes inside the cooler ought to be made of cast iron, to resist longer the action of the solution. The hot ore drops through *W*, and in striking the water, is immediately carried below the sheets of water and is so quickly enwrapped in it that but little dust is formed, which will be absorbed by the sprays, while most of the steam will be condensed. The bottom *T* has sufficient inclination to make the ore move as soon as it strikes it.



ORE-COOLING APPARATUS USED IN TROUGH LIXIVIATION.

By cooling the ore in this way, we have the additional advantage of increasing the temperature of the water used for base-metal leaching, without incurring extra expense or labor. The resulting temperature of the water will depend on its original temperature, the temperature of the ore and the proportion of water and ore used. By a laboratory test Mr. Hofmann found that a dark red-hot ore, dropped in three times its weight of water, raises the temperature of the latter from 60° F. to 95° F. To work the ore-cooling apparatus to advantage the hot ore is evenly charged by the hot-ore feeding machine illustrated in the Press of March 30th.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

From the official report of U. S. Patents in Dewey & Co.'s Patent Office Library, 220 Market St., S. F.

FOR WEEK ENDING APRIL 2, 1889.

400,730.—Spray Nozzle—John Bean, Los Gatos, Cal.

400,544.—Railway Vehicle—G. W. Brown, Los Angeles, Cal.

400,748.—Splicing Cables—John Collins, S. F.

400,832.—Coated Sheet Metal Pipe—J. P. Culver, Los Angeles, Cal.

400,564.—Rocking Chair—L. C. Gunn, San Diego, Cal.

400,681.—Grinding-Pan—Philip Hinkle, S. F.

400,461.—Harness Loop—E. B. Knapp, San Jacinto, Cal.

400,577.—Medical Compound—Levering & Curry, Los Angeles, Cal.

400,592.—Fin for Vessels—G. W. Napier, Los Angeles, Cal.

400,596.—Parallel Ruler—Phelps & Ellis, Eureka, Cal.

Note.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by mail or telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

Grinding Pan.—Philip Hinkle, S. F. No. 400,681. Dated April 2, 1889. This improvement relates to certain improvements in grinding pans, more particularly to certain details of construction. Among other things the construction enables the inventor to make a low compact pan which is easily separated into comparatively small portions for shipment.

Lamp Shade Protector.—Gustave A. Tank, S. F. No. 400,372. Dated March 26, 1889. This invention relates to that class of protectors for lamp and gas shades and globes in which a shield of some indestructible but translucent material—such as mica—is interposed between the shade and globe and the lamp or gas flame. The object of the invention is to provide simple and practical means for applying the protector.

Splicing Cables.—John Collins, S. F., assignor of one-fourth to H. H. Lynch. No. 400,748. Dated April 2, 1889. This invention relates to the art of splicing cables, and particularly to that method which, from the disposition of the strand ends, is known as "inlaid." The object is to make an inlaid splice without having to remove or in any way interfere with the soft core of the cable, said splice being of an effective nature and especially adapted to be readily made. The invention consists in the following-described successive steps: Dividing the opposing strand-ends or tucks back to their union with the cable; cutting off even with the surface of the cable one division of each tuck; taking one or more half-turns with the lay of the remaining divisions, one from each side, so as to form a splice-strand occupying the vacant score of the cable; unlaying the projecting ends of said last-named divisions so as to separate them into individual wires, and introducing said wires under the strands and against the soft core of the cable and laying them along and about the soft core throughout their length.

The Charleston.—The new cruiser Charleston is now taking in coal at Mission Rock in anticipation of her trial trip, which will take place at an early date. It is proposed to make a run of 300 or 400 miles and thoroughly test all the qualities of the vessel. She will probably take a cruise down through the Santa Barbara channel. On her return she will be speeded over the measured mile course in San Francisco bay.

The Sierra City people have been driving away from their town men supposed to be anti-mining spies. The local paper says: "There never was a gravel mine within several miles of Sierra City, and the few that are so near as that have never worked since they were enjoined."

D. O. Mills will visit his gold-mining properties in Alaska this summer.

MECHANICAL PROGRESS.

Revival of the European Iron Trade.

The English correspondent of the *American Manufacturer* recently wrote to that journal as follows:

There is every indication in the present condition of the various English iron-making centers that we shall shortly see a wide expansion of business and of prices in our metallurgical industries. The activity in shipbuilding, the dearness of coal and coke, and the increase in wages, are factors which cannot but lead to considerable additions to the cost of iron.

There is a strong demand for pig iron in all the districts—a fact which sufficiently indicates how strong the likelihood of advanced prices really is. Home consumers are purchasing in order to obtain their supplies before the inevitable advance takes place. An enormous demand from Germany and other continental markets is being placed in Cleveland, though shipments are delayed by unfavorable winds.

One fact which has to be seriously remembered in estimating the future of the iron-trade revival is that the demand for crude iron for the United States is abnormally low in comparison with what it was a year or so ago. If the manufacturing revival which many authorities expect to see in the States this year should really happen and should extend its beneficial influences to England, the British iron trade will enjoy a prosperity greater than it has been favored with for very many years. In the meantime the reports which I include in this letter will sufficiently show that metallurgical industry in this country has before it the prospect not of an unsubstantial inflation, but of a gradual and growing increasing prosperity.

The effect of the anticipated large additional expenditure upon naval armaments, to which reference in these letters has previously been made, is now being discussed more freely than ever among shipbuilders and producers of iron and steel for ship-building purposes. The assumption is that the Government will propose to spend £20,000,000 during the next three or four years, or at the rate of about £6,000,000 per annum.

It is believed that 14 ironclads will be built within this period, at a cost of nearly a million sterling for each vessel, besides about 50 cruisers and other smaller ships. From 250,000 to 300,000 tons of steel is needed for an outlay on this scale, besides the weight of the extra armor required. At present the shipbuilding yards are so fully occupied in all directions in producing new vessels for trading purposes that these further requirements, should they be actually sanctioned, can hardly fail, it is thought, to give still further strength to the prices of new vessels. In view, however, of current fears that the building of mercantile steamers is being overdone, it is quite possible that the Government orders may do no more than sustain current rates.

RUNNING LOCOMOTIVES WITH SODA INSTEAD OF COAL.—At the Baldwin Locomotive Works, Philadelphia, there are in course of construction four locomotives which are designed to run by soda, which takes the place of fire under the boiler. The engines are now nearly finished and will be shipped within two weeks to Minneapolis, Minn., and are to be run on the streets of that city, where steam engines are forbidden. The engine is about 16 feet long, entirely boxed in, with no visible smokestack or pipes, as there is no exhaust or refuse. The boiler is of copper, 84½ inches in diameter and 15 feet long, having tubes running through it as in steam boilers. Inside the boiler will be placed five tons of soda, which, upon being damped by a jet of steam, produces an intense heat. In about six hours the soda is thoroughly saturated, when the action ceases. A stream of superheated steam from a stationary boiler is then forced through the soda, which drives out the moisture and the soda is ready for use again. The exhaust steam from the cylinders is used to saturate the soda, and by this means all refuse is used. These engines are the first of their kind that have been built in this country. They will have the same power as those used on the New York elevated roads. Soda engines are used in Berlin and other European cities very successfully, and they also traverse the St. Gothard tunnel, under the Alps, where the steam engines cannot be used, because the tunnel cannot be ventilated so as to carry off the noxious gases generated by a locomotive.

A NEW INVENTION FOR ROLLING PIPE IRON. Probably the most marvelous hydraulic machinery in the world was recently placed in operation in the Wheatland rolling-mill, Penn. It is designed for rolling pipe iron. Huge slabs of iron, weighing hundreds of pounds, were pulled from a furnace, placed on a long iron bed, which moved forward, upward, downward, and laterally, pushing the mass through rolls. The whole operation required the attendance of only one or two employes, who controlled the machinery by a few simple levers. It is the only machine of the kind in the world.

COMPARATIVE COST OF IRON AND STEEL.—In a lecture recently delivered before the London Institution by Mr. Edward Riley, F. C. S., that authority gave a very complete and interesting *resume* of modern iron and steel processes, and effectively demonstrated the increasing efficiency of steel. Mr. Riley made the following comparison between the relative cost of iron and steel works to make 1000 tons of puddled bars, or 1000 tons of ingots weekly. Puddled iron works: Cost of plant, exclusive of land, $250,000; area of land required, 10 acres; number of workmen employed, 500; foremen, 10; pig used per ton of iron made, 22 cwt.; workmen's cottages, 200; fuel, 30 cwt. of coal; fuel used per week, 1500 tons. cost per ton, taking $10 pig, $18 25. Steel works: Cost of plant, $125,000; land required, 5 acres; number of workmen employed, 120; foremen, 4; pig used per ton made, 24 cwt.; workmen's cottages, 40; fuel, 4 cwt. coal and 3 cwt. coke; fuel used per week, 360 tons; cost per ton, taking $10 pig, $16 87½.

A NEW METHOD IN STEEL SHAFTS AND GUNS. John Shinn of Roxborough, Pa., recently patented an improvement in the manufacture of heavy guns. His invention is a new method of constructing large masses of steel, iron or bronze, by building them up of small parts previously cast or rolled and either welded together by electricity or brazed. He proposes to use small ingots of steel, which are not apt to contain concealed defects. The ingots are cold-rolled into longitudinal sections of the gun or shaft, welded together and bound by rings and jackets as in the old method. Cold-rolling is said to increase the torsional strength about 50 per cent, and the strength of the gun is made uniform throughout. The inventor claims that besides producing better work by his method, it can be done much more quickly and at an expense very much less than that of making guns and shafts from such enormous castings as are now used. Comparing the two methods, he says: "Mine is 50 per cent cheaper in gun-making and 75 per cent cheaper in shafts, and a heavy gun that takes two or three years to construct after the old plan could be turned out in from two to three months by my method." The necessity for improvement in the manufacture of shafts is shown from the fact that 222 ocean steamers broke their shafts between 1881 and 1884. The causes of breakage in these cases were, of course, concealed defects, as the shafts are always supposed to be perfect before being used. In increasing torsional strength and lessening the chances of concealed defects, Mr. Shinn expects to revolutionize this branch of steel-making.

TO HANDLE BLOOMS AND BILLETS.—At the Bellaire mill, Pennsylvania, there is now in operation an improved apparatus devised by O. P. Mason, for facilitating the handling of steel blooms, billets and slabs, in a rolling-mill. The tables by means of which the ingot is led to the rolls have driven rollers on which the ingot lies, and by which it is moved backward and forward as it is passed to and fro through the rolls. A horizontal shaft is arranged on bearings under the rollers, and provided with projecting arms, of crescent shape at right angles to its axis, the arms extending upward between the rollers, and the shaft being operated by a pinion working into a rack actuated by a hydraulic cylinder, the length of the rack being such as to allow the shaft to make one complete revolution. With this construction the ingot, as it lies on the rollers, can be readily moved from one side to the other, the crescent-shaped arms catching the piece on its lower corner and tumbling it over, as the horizontal shaft is put in motion.

STEEL WELDING PROCESS.—Mr. W. B. Middleton, manager of the Penn Iron Works, Lancaster, has a process by which pieces of steel may, at a welding heat, be perfectly welded together after they have been coated with a solution of silicate of soda or other solution in which silica is contained. In practice, satisfactory results have been obtained by dipping the pieces of steel to be welded in a solution of silicate of soda, or by pouring the solution on them, bunching together the pieces to be welded, and heating them to an ordinary welding heat, and then passing them through rolls. This is the process followed with large pieces, but smaller articles can be welded under the hammer when treated previously with the solution. Mr. Middleton states that the process is applicable for reworking old steel rails and other heavy pieces, and that it renders certain kinds of steel scrap highly valuable which formerly were almost worthless.

COMPRESSED AIR AS A MOTIVE-POWER.—Compressed air is now being extensively employed as a motive-power in Paris instead of steam. The central station comprises 12 boilers and 6 compound engines, and the air which is compressed to six atmospheres is stored in receivers, and distributed as required in various industrial establishments. The compressed air also serves as a refrigerating medium, which can be utilized for sanitary and other purposes. It is intended to erect covered markets, which will be provided with cooling chambers, supplied with compressed air from the central station.

ACCORDING to Herr Leonhardt, a German engineer, the number of locomotives in use on German railroads was 12,450 in the year 1885–86, the average age being 12.49 years. Fifty engines built previous to the year 1850 were still in use at the date referred to, the oldest of which dated from 1845.

NOISELESS GEARING.—Where noise from gearing is objectionable, and smooth working a necessity, vulcanized fiber is being used for teeth in England with success. It prevents noise and wears well.

SCIENTIFIC PROGRESS.

The Cause of Earthquakes.

At the meeting of the Manchester Geological Society, held on Feb. 12th, Thos. Oldham read a paper on "The Causes of Earthquakes, or Dislocation and Overlapping of Strata, and of Similar Phenomena." The author said this was a subject which had caused much perplexity and doubt in the minds of many eminent geologists, in endeavoring to account for the cause of some of the greatest phenomena in nature continually taking place. These were the cause of earthquakes, the dislocation and overlapping of strata, and the submerging and upheaval of continents, etc. The hypothesis he intended to submit was based upon purely physical laws, and he had often felt surprised that such views had not previously been promulgated. He must premise by stating it had been ascertained that this globe is about nine miles smaller in diameter at the equator than at the poles; in the next place, it was known that the globe rotates on its axis at about 26,000 miles every 24 hours, which is nearly equal to the speed of a cannon-ball.

Another thing that had been ascertained was that the axis of the globe is gradually altering by becoming more oblique, and that it requires about 39,000 years before this alteration arrives at its maximum. When they took into consideration the great velocity at which the globe rotates, it was evident that a large amount of centrifugal force must be exerted, and as nature never did anything without a motive, it would be seen that this force is the cause of the globe being nine miles different at the equator and the poles. As the axis got gradually more oblique, so the direction of the equator would alter.

It is supposed that the crust of the earth is only about 15 or 16 miles in thickness, and below that distance there is a mass of incandescent minerals. This has been proved, in one way by mining, where they find in sinking the first 1000 feet the temperature rises very considerably and becomes greater as they get lower. In order to bring these things practically before them, he would suppose a model to be made to represent the globe, in exactly the same proportions as they stood toward each other, and for this purpose he would take a mass of some plastic material, say potters' clay, of sufficient consistency to allow of its being formed into a sphere of about nine feet in diameter; he would then pass an iron rod through it, and connect the whole with a steam engine to obtain the required motion. If they gradually raised one end of the axis, the equator would get more oblique, and more toward the north or south as the case might be. It is known that centrifugal force acts not only at right angles to the earth, but has also a lateral motion.

Astronomers told them that the deviation of the axis arrives at its maximum every 39,000 years, so that consequently the south pole, when the climax occurs, would occupy the place where the north pole is now. It was supposed that the last great climax was a glacial one, and there are plenty of evidences to prove this. In the River Amazon, which is now exactly on the equator, there are many evidences of glaciers, and in like manner these are also come across in northern latitudes.

When they looked upon human life in comparison with geological ages, the life of man seemed but an atom, and their historical records only went back 2000 years, anything further being purely legendary. It was supposed that at one time the spaces now occupied by the Atlantic and Pacific oceans were large continents, and when naturalists go up mountains, they frequently come across beautiful specimens of conchology which could only have got there by the upheaval of oceans. These changes, the author concluded, were the source of much perplexity to geologists, and were of great interest.

A CURIOUS THEORY.—Although geologists are accustomed to deal with considerable alterations of level as one of the causes operating to bring about profound changes in the topography of many regions, it has always seemed difficult to conceive, remarks a recent writer, that the vast depressions in the face of the earth now occupied by the sea could ever have been subject to such tremendous changes as would be necessary to convert them into land. Many geologists, therefore, appreciating this difficulty, are inclined to believe in the general permanence, during all time, of the great oceanic beds and of the continental areas. To account for the origin of the oceanic basins, a writer in a recent issue of the *Geological Magazine*, proceeding on the theory of Prof. Darwin that the moon broke away from the earth more than 50,000,000 years ago, expresses the opinion that the ocean basins may be the scars left by the breaking off the moon's mass, when that prodigious segregation took place, and that the basement rocks of the continents are fragments or portions of the crust, which had already been in a solidified state, and which were left behind.

NEW THEORY ABOUT DIAMONDS.—Prof. Simmler brings forward the somewhat plausible theory that the basis of diamond formation is liquefied carbonic acid. Indeed, facts observed by different savants tend to show, it is said, the presence of this agent in the coating of the most valuable gems. Upon the bursting of such crystals there are often found to occur two liquids in the cavities, the one behaving like water, the other liquid carbonic acid. On one occasion, indeed, it was observed that the liquid in a quartz crystal, which was dashed to pieces, scattered its contents around with a great noise, burning holes in the handkerchief wound around the hands of the experimenter. The acid contents itself had disappeared. Under these circumstances, Mr. Simmler argues that if carbon be soluble in liquid carbonic acid, it would then only be necessary to subject the solvent to slow evaporation. The carbon would thereby be deposited, and by taking proper care assume crystalline forms, and in evaporating quickly, the so-called black diamond, which, in the state of powder, is much used for polishing the colorless diamond, might be produced.

A RICH FIELD FOR THE SCIENTIFIC STUDENT. Some one has very correctly remarked that the Pacific Coast is almost a virgin field for the scientific student. Nowhere in the world can the history of creation be studied to better advantage. The geological survey of the State, which was undertaken in 1860 for the benefit of the mining interest, was brought to a close in 1874, and very little knowledge has been acquired since. It is known that, to speak familiarly, this was probably one of the last parts of the world to be finished by the hand of the Creator; the Sierra was still quaking and upheaving when volcanic agency had exhausted itself elsewhere. Parts of the Coast Range may have been lifted up and the rocks tilted on edge when man lived on the flank of the Sierra in the later tertiary age. High up on the same Sierra are cretaceous rocks which are obviously of marine origin; there must thus have been a time—and probably a long period—when Lassen county was washed by the waves of the ocean. Nearer home, on the Sacramento and in parts of Contra Costa county, are abundant pre-historic remains which have never been thoroughly examined. Here alone there is a field where the academy may find opportunities of usefulness. The whole State is full of marvels to the scientific mind, and it is time that they were investigated by competent persons.

WHEN THE WORLD WAS YOUNG.—According to Mr. Proctor, the present denuding effects of air and water upon the earth's surface are absolutely as nothing compared with the denuding forces which must have been in operation when the earth was young; the oxygen and nitrogen of the air are but a residue of what was once there; but besides these gases, now in due proportion to support the earth's life, there were immense quantities of carbonic-acid gas, of sulphurous acid, sulphureted hydrogen, chlorine, boracic acid, and other destructive gases, some ready to assume the liquid form, and thus to be still more destructive. Mr. Proctor thinks there must also have been immense quantities of water in the form of vapor; in fact, the presence of that primeval atmosphere must have been so great, he thinks, that the waters of such oceans as then existed could have turned into steam only at a temperature so far above the boiling point at the present atmospheric pressure as to have caused the surface of the ocean to actually glow with inherent luster. The water vapor in the air must also have been steam at a high pressure and intensely hot, and the rains falling then must have been in the form of torrents of hot water, impregnated with most destructive acids and falling on intensely heated rocks.

THE RAYS OF SUNSET.—Prof. Rovelli has published the result of his studies concerning the colors of twilight, from which it appears that red and orange tints predominate when the air is dry; on the contrary, yellow, and especially green, characterizes air charged with vesicular vapor. Prof. Rovelli studied the colorations of the air and their successive modifications in various cases, and in the various parts of the crepuscular region, in measure as the sun disappears from the horizon; also the same phenomena at the advent of "aurora with rosy fingers," and from them drew conclusions based upon the theory of the colors of the solar spectrum. Observation had already shown that the warmest colors of the spectrum predominate during a period of fine weather, while a yellow tint, followed by a greenish twilight, is the index of great humidity. Again, the atmosphere may be considered as formed of two strata, the lower of which containing clouds and dust, and the upper of which is more transparent; these two strata, as regards their refrangibility and absorption, appear differently in the presence of the rays that traverse them.

POSSIBLY the reader may draw his own conclusions from the following, which is now going the rounds: Mr. Friese Greene, a British photographer, has actually produced a picture with only the light issuing from his eye. Having stared for 15 seconds at a 5000-candle electric arc only three feet away, he closed his eye and quickly brought it over a sensitive plate at a distance of one inch. The result was a very faint but distinct image of the arc and the carbons, due, probably, to momentary phosphorescence of the retina. A second attempt failed, and gas lights proved too weak to produce effect.

TEMPERATURE ON THE MOON.—Astronomers claim that the moon's surface is subject to a degree of heat corresponding to about 500° of Fah. scale, when exposed to the sun's rays, and that it cools down to 250° below zero when not so exposed.

GOOD HEALTH.

GETTING THE BEST OUT OF LIFE.—The London *Standard*, in discussing whether it pays to try to live to be a hundred years old, gives some useful suggestions. It says: "The man who really gets the best that can be got out of life is the man who, with a fairly good constitution to begin with, is ready to squander it at any moment and on every occasion in a sufficient cause. He keeps no account of profit and loss with his vital energy; he sees work to do and he does it, he sees pleasure to be enjoyed, and he enjoys it. He is alive all his life save when he sleeps; and he wakes from each fresh slumber looking the world cheerfully and courageously in the face, and ready and even eager to be a combatant when there is a good, honest fight, and a runner, when there is a good, honorable race afoot. He may not live to be 100, but he may well live to be 70, 75, or even 80. He may have a career, if not so conspicuous, yet as active, as varied, and as restless as that, say, of Mr. Gladstone, and yet not be really old when time registers him among the aged. 'Better fifty years of Europe than a cycle of Cathay;' and better 20 years of uncalculated activity than the slow pulse and measured step of the circumspect snail that creeps surely on to 100. We are not denouncing centenarians. They are like angels' visits, few and far between, and they are too rare not to be welcomed. Moreover, we doubt not that they deserve their length of years. But it would be a misfortune if it was ever thought an object of life to live very long. The object of life is to live, live nobly, live bravely. As Shakespeare says: 'Ripeness is all.'"

THE PHILOSOPHY OF EATING.—Growth and waste and repair go on in a nearly uniform way the whole year through, but the amount of food necessary for these operations is surprisingly small. The generation of bodily heat requires a more variable quantity of food. In winter, with the temperature of the external air at zero, the temperature of the blood in healthy persons is 98 3°, and when the heats of summer drive the mercury of the thermometer near to or above that mark, the blood still registers 98.3°. The marvelous mechanism by which this uniform blood temperature is maintained at all seasons, it is not necessary to consider, but it must be evident to every one that the force needed to raise the temperature of the whole body to nearly 100° in winter is no longer needed in summer. The total amount of food needed for repair, for growth, and for heating, physiology teaches us is much less than is generally imagined, and it impresses us with the truth of the great surgeon Abernethy's saying, that "one-fourth of what we eat keeps us; the other three-fourths we eat at the peril of our lives." In winter we burn up the surplus food with a limited amount of extra exertion. In summer we get rid of it literally at some extra risk to health, and, of course, to life. We cannot burn it. Our vital furnaces are banked, and we worry the most important working organs with the exertion of removing what had better never have been taken into the stomach.—*Selected.*

A NEW VICE.—The latest vice in the way of intoxication is reported from Boston. The material employed consists of the vapor of naphtha, which is simply inhaled, and induces, so the inebriates say, a particularly agreeable exhilaration. Not even basheesh, it is understood, begets more fascinating dreams or more gorgeous visions of splendor. The girls in the rubber factories, of which there are a great number in Boston and its neighborhood, are greatly addicted to this novel form of drunkenness. In such establishments naphtha is used in enormous quantities to cleanse the rubber, being kept in big boilers, closed against the air. To the valves of these boilers the young women employes readily obtain access, and breathe the exhalations therefrom, some unlucky accident having betrayed to a chance experimenter the abominable secret. The notion is said to have been brought originally from Germany by immigrant laborers in petticoats. Now the manufacturers propose to put a stop to the evil by keeping the valves carefully locked. An overdose of naphtha fumes brings on hysterical convulsions and other unpleasant symptoms. The habit, long followed, causes a swelling of the face and other parts of the body, with dropsy to follow, and sometimes epilepsy.

FIVE WAYS TO STOP A COLD.—First—Bathe the feet in hot water and drink a pint of hot lemonade. Then sponge with salt water and remain in a warm room. Second—Bathe the face in very hot water every five minutes for an hour. Third—Snuff up the nostrils hot salt water every three hours. Fourth—Inhale ammonia or menthol. Fifth—Take four hours' active exercise in the open air. A ten-grain dose of quinine will usually break up a cold in the beginning. Anything that will set the blood actively in circulation will do it, whether it be drugs or the use of a buck saw. But better than all, if your cold is inveterate or serious, consult your family physician, and at once.

A NOTABLE SURGICAL OPERATION.—A very remarkable surgical operation was recently performed at Bridgeport, Conn., upon Mrs. Ida Brinsmade. The operation required the utmost skill and delicacy. It consisted of cutting through into the kidney to remove an abscess which had formed on the inside of that organ. The lady is 32 years of age. In the process of the operation the diagnosis of the physicians was found to be entirely correct. The operators cut alongside the backbone, below the lower rib, clear down to the kidney, to a depth of 3½ inches. The utmost nicety was required in order to strike the kidney, as half an inch variation would have done incalculable damage. The abscess was found, and over a pint of pus was removed after the incision had been made. The patient bore up through it all in a heroic manner. She is doing as well as could be expected, and there is every prospect that the operation will prove a complete success, and full recovery ensue.

TIRED EYES.—People speak about their eyes being fatigued, meaning that the retina, or nerve portion of the brain that does the seeing, is fatigued, but such is not the case, as the retina rarely tires. The fatigue is in the inner and outer muscles attached to the eyeball, and the muscle of accommodation which surrounds the lens of the eye. When a near object is to be looked at, this muscle relaxes and allows the lens to thicken, increasing its refractive power. The inner and outer muscles are used in covering the eye on the object to be looked at, the inner one being especially used when a near object is to be looked at. It is in these three muscles mentioned that the fatigue is felt, and relief is secured temporarily by closing the eyes or gazing at far distant objects. The usual indication of strain is redness of the rim of the eyelid betokening a congested state of the inner surface, which may be accompanied with some pain. When the eye tires easily, rest is not the proper remedy, but the use of glasses of sufficient power to aid in accommodating the eye to vision.

MIND-DESTROYING DRUGS.—Dr. Wilkins, superintendent of the insane asylum at Napa, in a recent conversation as to the number of young men and women at present in the asylum from the use of opium, morphine, cocaine and kindred narcotics, stated that the subject had given him more trouble than all other causes of insanity combined. He said that among his patients were those whose minds had become unbalanced through drink, family afflictions, business losses and from other causes, but the worst cases were those whose minds were destroyed through the use of narcotics. The number of patients from this cause is rapidly increasing, and there have been more men and women committed during the past six months suffering from dementia occasioned by drugs than there was from the same cause during the ten previous years. Said he: "The statement may appear incredible, but it is borne out by facts. Narcotics are a more prolific source of insanity than all other causes combined."

USEFUL INFORMATION.

A NEW SOLDER.—A soft alloy, which adheres so firmly to metallic, glass and porcelain surfaces that it can be used as a solder, and which is invaluable when the articles to be soldered are of such a nature that they cannot bear a high degree of temperature, consists of finely pulverized copper dust, which is obtained by shaking a solution of the sulphate of copper with granulated zinc. The temperature of the solution rises considerably, and the metallic copper is precipitated in the form of a brownish powder; 20, 30 or 36 parts of this copper dust, according to the hardness desired, are placed in a cast-iron or porcelain-lined mortar and well mixed with some sulphuric acid having a specific gravity of 1 85. Add to the paste thus formed 70 parts (by weight) of mercury, constantly stirring. When thoroughly mixed, the amalgam must be carefully rinsed in warm water to remove the acid, and then set aside to cool. In 10 or 12 hours it will be hard enough to scratch tin. When it is to be used it should be heated to a temperature of 375° C., when it becomes as soft as wax by kneading it in an iron mortar. In this ductile state it can be spread upon any surface, to which, as it cools and hardens, it adheres very tenaciously.—*Exchange.*

SCREW-MAKING MACHINERY.—*Invention* states that the first instance known of machinery being applied to the making of screws was in France, in 1569, by a man named Besson, who contrived a screw-cutting gauge to be used in a lathe. In 1741 Besson's device was improved by Hindley, a watchmaker of York; and for a long time the watchmakers of England employed the latter's method in making the small screws used in their work. The first English patent appears to have been issued to Job and William Wyatt, in 1760, for three machines—one for making blanks, another for nicking the heads, and a third for cutting the threads. Between that date and 1840 about 10 patents were issued.

THE OLDEST WINE IN AMERICA.—A newspaper paragraph has been going the rounds to the effect that the oldest wine in America dated back to 1790 or 1791, and was to be found in a wine-cellar in the city of Savannah, Ga. The Germantown (Pa.) *Telegraph*, however, says that Mr. Ellwood Johnson of Germantown has a bottle of wine made in 1760 by Thomas Livezey from grapes grown on the Wissahickon Hill about Allen's Lane Bridge. When the British were in and around Philadelphia, Mr. Livezey buried a cask of wine in his millrace. Mr. Johnson can claim the oldest wine, undoubtedly.

TO PRESERVE PRESSED LEAVES.—To preserve leaves and other parts of plants properly, they should be placed between sheets of blotting paper, and the papers should be changed once a day for two or three days. They should be dried as rapidly as possible, by passing a warm flatiron over the paper each time the change is made. They should be kept under moderate pressure at first, and to insure even pressing, it will be well to place a stiff piece of card-board or straw-board at intervals between the sheets. When the drying appears to be well advanced, the pressure on the specimens may be increased.

SODA FOR CLEANING LAMP CHIMNEYS.—Take a piece of saleda the size of a walnut, put into a quart of soft water, put your lamp-burner in it (an old tomato can is good enough), set it on the stove; after boiling five minutes remove the burner, and when put back on the lamp will be as good as new. All the carbon on the old burners should be removed once a month. Another way to keep your wicks from smoking is to immerse them in strong vinegar and dry them thoroughly.

PAPER AS TOUGH AS WOOD.—A plan for rendering paper as tough as wood or leather it is said has been recently introduced on the continent; it consists in mixing chloride of zinc with the pulp in the course of manufacture. It has been found that the greater the degree of concentration of the zinc solution, the greater will be the toughness of the paper. It can be used for making boxes, combs, for roofing, and even for making boats.

MINING UNDER A LAKE.—At the new hematite mine of the Cleveland Iron Mining Company, located under Lake Angeline, there is a scene of the greatest activity, noticed at any of the properties, new or old, in the region. The company, as is generally known, has a 200 foot vein of ore under the lake; it probably has even a greater width than that, but this much it has proven by exploration.

WROUGHT-IRON PIPE WORKS.—There are 24 wrought-iron pipe works in the United States—one in Massachusetts, two in New York, 14 in Pennsylvania, one in Delaware, one in West Virginia, two in Ohio, and three in Illinois. Of the 14 in Pennsylvania, six are in Pittsburg. All the others are in the eastern part of the State, four being in Philadelphia.

REWELDING OLD BALE TIES.—A machine has been invented for welding cut bale ties. By its means cut ties that accumulate at the compresses, which are so well known in the South, can be very quickly made up into proper lengths for use. At the present time cut band ties, though in large quantities, are worthless except as scrap iron.

ELECTRIC-LIGHT CARBONS.—Six years ago all the carbons burned in the electric lights of the country were made in one room in Boston by ten men. There are now 150 tons consumed daily, and of this number 100 tons are turned out in the 20 carbon furnaces of Cleveland.

A PROFITABLE PURCHASE.—The Alaska Commercial Company have paid into the United States treasury since the "Seward purchase" was completed $8,000,000. Russia received for the whole country $7,200,000.

CARPET MANUFACTURE IN PHILADELPHIA.—The carpet manufacturers of Philadelphia have 3750 looms in use, employ 17,800 hands, and manufacture annually 7,500,000 yards of carpet at a value of $44,970,000.

ARTIFICIAL FISH-DRYING.—The practicability of drying fish with artificial heat has been successfully tested at Canso, Nova Scotia. This new method will be tried on an extensive scale the coming season.

GAS VS. COAL FOR HEAT.—Fifteen cubic feet of gas will give as much heat as one pound of bituminous coal. Ten cubic feet of air is required for the perfect combustion of one cubic foot of gas.

RAPID ACCUMULATION OF WEALTH.—The accumulation of wealth in the United States is equal to one-third of the daily accumulation of all mankind outside of this country.

THE great number of big steamships that years ago filled the Mississippi are fast disappearing. The railroads have taken their places.

THE TANNING of boa constrictor skins forms a branch of industry in Hamburg, N. J. They are made into pocketbooks, principally.

A QUICK EXTINGUISHER.—It is stated that a solution of pearlash in water, thrown upon a fire, will extinguish it immediately.

DOUBLING the diameter of a pipe increases the capacity four times.

ELECTRICITY.

A GRAND ELECTRIC TRIUMPH.—The latest novelty in improvements in office-building is the "electric service" system for automatic regulation of heat. This invention has just been placed in the new market and Fulton National Bank building, corner Gold and Fulton streets. The heat in this building will be under electrical control, and every tenant can have the temperature he desires without paying any more attention to the matter than he would to the running of the furnace or boiler. Thus, in two adjoining rooms where a consumptive in one wants a temperature of 90 degrees and a full-blooded fellow in the other wishes only 60 degrees, each gets just what he desires. The engineer in the engine-room can tell whether any room is too cold and can instantly send additional steam into the office whose thermostat placed before him reveals the necessity. The landlord saves from 25 to 40 per cent on fuel, and the tenant escapes severe colds and general discomfort. If a new tenant comes in, he merely notifies the engineer of his individual tastes and the heat is regulated accordingly.—*Progressive Age.*

IS LIGHT AN ELECTRICAL DISTURBANCE?—Prof. Oliver Lodge, in a very interesting study on the modern view of electricity, says that light is an electrical disturbance, and that light waves are excited by electrical oscillations. Our present system of making light artificially he characterizes as wasteful and ineffective. We want a certain range of oscillation—between 7000 and 4000 billion vibrations per second. Perhaps, speaking theoretically, this is sound reasoning; but practically, we don't see how anything that serves a purpose as well as we have learned to serve it can be wasteful, nor how, when a thing is accomplished satisfactorily and thoroughly, it can be called "ineffective." It *must* be effective because it succeeds, and must be regarded as economical at least until we can find a cheaper means.

AN ELECTRIC POSTAL RAILROAD.—Three hundred miles an hour is the proposed speed for the electric postal railroad of the future. An experimental line has been erected at Laurel, 20 miles from Baltimore, Md. A compromise between the pneumatic tube and the ordinary railroad carries a miniature train of two cars, solely for mails and light parcels, without any attendance. The road has three rails—one above the car, for carrying the current, and two below, which carry the cars. The cars are built of sheet iron, and are two feet square and 21 feet long. Speed will be regulated, and power or brakes applied by electricity solely. If the experiment at Laurel succeeds, it is stated that similar roads will be laid between Baltimore and Washington and elsewhere.—*Exchange.*

ELECTRICITY is being more and more used for the purification of kaolin and other porcelain clays. The clay is sifted on to a rapidly revolving horizontal plate, which is surrounded with powerful electro-magnets, which retain the particles of iron. From this the clay passes to a second plate, which removes the last traces. The process is said to be comparatively cheap and very rapid, and since its introduction many clays, hitherto rejected as containing too much iron, have become of value for the manufacture of pottery.

A NEW TYPE OF DYNAMO, called the wheel-armature dynamo, has been brought out in Berlin. Details of the construction are lacking, but it is said that it is possible to construct it without core, without cotton insulation and without copper. The armature takes the form of a grating of fine wrought-iron rods, with no other insulating material between them than the air. The rapidity with which electric science is developing already surpasses all former records. "What will the harvest be?"

HEAT FROM GAS.—While the electric light is gradually taking the place of illuminating gas in Germany, the latter article is evidently going to meet with an extensive sale in another direction, on account of its considerable evolution of heat. In comparison with the electric light, it is this property which is, apart from minor brightness, considered as its principal deficiency. It is stated that the heat from equal amounts of gas and coal is in the proportions of 26 to 15.

THE BRUSH MACHINES IN ENGLAND.—The Anglo-American Brush Electric Light Corporation, Limited, have just secured an important contract for the supply of about 40 sets of combined engines and dynamos of their special design, and have now in hand orders for nearly 50 sets of apparatus of this pattern. The design has met with much favor from European Governments since its introduction, and has been largely adopted for ships of war and other vessels.

THE LONGEST DISTANCE that the electric current has yet been successfully carried for lighting purposes is less than six miles. At Portland, Me., the Westinghouse Electric Co. is preparing to utilize a water-power 12 miles distant from the city for electric-lighting purposes.

THE EDISON SYSTEM of electric-lighting has sufficient underground wires in New York City to supply 200,000 16-candle power lamps.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

DRYTOWN.—Cor. Amador *Ledger*, April 6: Work on the Drytown Con. mine is progressing. The pipe is all laid, and the trestle-work across the creek completed. Two loads of the framing for the hoisting works was hauled in this week, and they are now waiting for the machinery. The Gover mill has been idle for a couple of days on account of the breaking of the rock-crusher. They are now putting in a new one in the ore-house near the mine instead of in the mill where the old one was. The water skips and pumps are kept busy at the mine taking the water out of the shaft. It will take some time before they reach the bottom. Then the intention is to sink 200 feet deeper. At the Cosmopolitan the new boiler has been placed in position. A new station has been made at the 300-foot level, and some splendid rock encountered. The Potosi mill is still running on ore taken from the North California mine.

SUTTER CREEK.—Cor. Amador *Ledger*, April 3: Work at the North Star is almost suspended on account of the expiration of the two years' lease being so near at hand, and there being nothing in sight to justify the stockholders in buying the mine. To-day they are cleaning up at the Wildman, and the plates look well. Knight & Co. have just received a contract for two 17-inch pumps and one hydraulic engine to go to the Marguerite mine.

BUNKER HILL.—Amador *Ledger*, April 6: The big tunnel of the Bunker Hill is stopped. A chart of the mine was taken and sent East; the popular impression is that the mine will change owners. The directors of the North California met in Sutter Creek Tuesday; the mill will be closed down and prospecting will be carried on extensively. The Keystone is prospecting on a very extensive scale.

NORTH CALIFORNIA.—*Dispatch*, April 6: The mill was closed down for a few days last week, as one of the flumes was blown down on the ditch. It has since been repaired and the mill is pounding away again.

SALE.—Mr. Duff Reaves has bought the Evans quartz-mill below Plymouth and is moving it up to his mine, where he proposes to set it up and operate it. Mr. Gordon of Amador City is going to rebuild the mill. Mr. Reaves has an unlimited amount of good quartz to put through the mill when in order to work.

ZEILE.—The shaft at this mine has been sunk to a depth of 1160 feet, at which place it is the intention to run a level. The lowest level is about 100 feet above this place. During the sinking from 10 to 15 stamps were "hung up." The mill will run to its full capacity hereafter.

OVERPLUS.—The Huntington mill is kept running steady, reaping a harvest in the way of bullion; it is paying well.

Fresno.

MT. RAYMOND DISTRICT. — Fresno *Review*, March 29: Fred McMillan of Mt. Raymond mining district, situated in the northern part of this county, arrived in this city yesterday and reports that operations in the mines in that district are very active. The Star Mining and Reduction Co., the principal company operating there, have just completed their concentrating mill and commence reducing ores on the 1st of April. The mill has a capacity of reducing 125 tons of ore daily. Their Hallidie cable tramway is now in operation, conveying ore from the mine to the mill, a distance of one and one-half miles, and is a perfect success as a transporter. There are about 60 men employed at present, and about 100 will be engaged as soon as the mill starts. Reports speak favorably of a San Francisco company commencing operations on the Harlow group of mines this season. The operations of the Star company will certainly demonstrate that the lead and silver mines of that district can be successfully and profitably worked, and this season will place Fresno county among the lead and silver producers of the world. There is an unlimited amount of galena ores there, which is only awaiting the miner with capital to make them great metal producers. Mining operations are active at Grub gulch. The Surprise mill is running day and night, and the mine is reported looking better now than ever. A large force of men is employed. The Gambetta mine, owned by John Haley, is still being profitably worked. The Crystal Spring M. Co., which commenced operations on its mines a year ago, but suspended work last fall, will again commence operations in a few weeks.

Inyo.

BEING WORKED.—Inyo.*Register*, April 4: The mines on Fish Spring hill are being worked by Messrs. Welch, Daly, Mairs and others. Gold ore is being taken out and worked in Henry Melone's arastra.

Monterey.

LOS BURROS.—Monterey *Democrat*, April 6: The heavy rains left the ground in excellent condition for prospecting, and in consequence all the miners, prospectors and every one else of the camps who are not busy have joined the pan and shovel brigade. Sluicing was being done at a lively rate on Main street, Saturday, all along with very satisfactory results. Sunday quite a crowd went to the Old Man of the Mountain placer grounds to try their luck. Much fine gold and several nuggets were taken out. Wild Bill took two from one pan of dirt for which he was offered $10. Several new discoveries are reported in the last few days. A party from San Jose, Messrs. Keeler, Jackson & Lovell, have found and located a very rich ledge. The Enterprise Development and Tunnel Co., J. F. Holmes, president, are to begin operations in a few days, on their property in this district. The Cruikshank ledges are looking well. The two drifts from the main level show about 140 feet of the ledge averaging about five feet in thickness and showing free gold the entire distance. Capt. Jack Sargent reports favorably from the Willow Creek country. Pete Gillis struck a very rich pocket on his claim, the San Juan, one nugget weighing $20. From all indications this district will before long be one of the most important in the State, the gold running belt extending from the ocean to the Lion's Den country, a distance of about 15 miles. Gold has been found the entire length, from fine colors to a nugget weighing $41, and as the main and most important mines and prospects of the camp, viz.: Sure Pop, Melville, Last Chance, King, Ajax, Wild Bill, and many others, lie almost in direct line, it shows that it must be one continuous fissure vein or mother lode having its many spurs and feeders. That the gold-bearing ledges are permanent below the surface is proved by the Cruikshank lead, which is the only mine that has been prospected any depth. This mine at a depth of 150 feet shows the ledges three times the size as at the surface and as rich in proportion. The only drawback seems to be that the richest prospects are owned by men who have not the money to develop them at once, and it is only of late that this country has been of much note among outside mining men and capitalists. This is owing to the fact that it can only be reached by a long and tedious route which can only be traveled on horseback, but the proposed county wagon-road across the mountains will do away with this inconvenience and facilitate opening of the mines.

Nevada.

SHAFT.—*Tidings*, April 6: The shaft of the W. Y. O. D. mine is down 440 feet, and sinking is being continued for a 500-foot station. The ledge improves with depth.

NORTH BANNER.—The annual meeting of the stockholders of the North Banner M. Co. was held this afternoon. The reports of the various officers showed that the mine is profitable property, with good promise for the future. Directors as follows were elected, to serve for the ensuing year: Geo. Fletcher (Pres.), John F. Kidder, E. H. Brown (Treas.), A. Mattison and W. E. Brown, the last named of San Francisco. M. J. Farrell was elected as secretary, and John Skewes as superintendent.

Placer.

MICHIGAN BLUFF.—Placer *Herald*, April 6: The *Herald* is indebted to A. Rodgers for the following mining news from Michigan Bluff and vicinity: Robert Watson has been made superintendent of the Dam claim. The company will soon begin an air shaft, which is necessary to the working of the mine. This shaft will be 500 feet in depth. The tunnel, which is 3600 feet in length, has been straightened in places and T rails have been laid. During the last year a gravel channel running nearly north and south has been struck. This channel is 240 feet wide and holds rich gravel, but will require hoisting apparatus, as it is lower than the old channel and carries a large body of water. The Co. and those who have visited the mine think it is the Mayflower channel, as the gravel is similar. F. Chappellet & Co. are running a tunnel into the Eureka claim, which is three miles above the Dam. At the Hogsback a drift is being run across the channel in search of the other rim. The Red Point and Hidden Treasure mines are paying big. The Sutcliffe boys have been doing well in El Dorado canyon. They have found new ground in many places in the bed of the canyon which has paid handsome dividends. They haven't said much about their claim, but it is known that it has paid as high as $1500 a week for several consecutive weeks. Two mining experts have been examining the ledges in El Dorado canyon, and they think systematic prospecting would discover rich quartz mines there. William Muir is taking out good pay at the Oro, which is situated just above the old Weske mine. The gold is coarse and heavy.

Shasta.

MINING OUTLOOK.—Redding *Free Press*, March 30: The mining outlook, so far as quartz is concerned, was never better. It is true, if there were more snow in the mountains, water in the creeks and springs would hold out longer and be a blessing to the prospector and his pack animals away from living streams, but the numerous quartz-mills with water for motive-power are pretty generally located on such creeks as do not depend altogether on the snowfall along the watersheds for their midsummer water supplies. In the Old Diggings district, placer mining still occupies the attention of a few old residents, but the weather this season has not been very kind to them. The quartz miners, however, have bright prospects, and as there are now several big mining corporations interested in property in the county, there is no reason under the sun why the quartz branch of our mining industry should not flourish as it never has before.

Sierra.

COMMENCED CRUSHING.—Nevada *Transcript*, April 4: Holcomb, Moore & Callahan, who are engaged in prospecting the North Alaska (formerly Graphic) quartz claim, which is situated a mile above Plum Valley, Sierra county, have erected a four-stamp mill there, and about a week ago began a test crushing. If the results are favorable they hope to be able to interest Eastern capitalists in the property. The new owners claim that the Graphic Co.'s failure was due to the fact that they worked upon a break from the main ledge instead of upon the ledge itself.

SIERRA CITY.—*Tribune*, April 6: Sierra City is going to be the liveliest and best mining town on the coast this summer. It is a settled fact that we are going to have a boom. We have not had quietness for the past few months for nothing. The people here have just been preparing for the boom. No town in the State has as many rich mines as Sierra City, and no district has as many good prospects as old Sierra City; and together with all these good things, at no place in the State can you find as many experienced and capable men for working a mine as you can right here.

Siskiyou.

RIVER MINING.—Yreka *Journal*, March 29: The river companies on the Klamath are all getting ready for work, and will soon put in wingdams, as the river is not likely to be any higher this season, with prospects of low water much earlier than for many years past. Shasta river, for some distance above its mouth, is becoming a rich mining camp, several of the claim-owners having taken out considerable dust during the past year. Henry Marion, who has a ditch in that locality, started below a few days since to secure machinery for elevation of water from Shasta river, in order to gain a pressure for hydraulic operations. The other companies all work with sluices, shoveling the pay gravel from the banks. Pullen is pushing things at Klamath river, getting ready to put his wingdam into the stream. He will put up a derrick, and we understand he has a good paying claim. Jillson & Co. hydraulic as often as they can collect enough water in their reservoir. We did not learn what the prospect is. It is very unfortunate that there is so little water.

QUARTZ.—Messrs. Heckathorn & Wademan have found another rich pocket in their quartz mine on Greenhorn creek, a short distance south of Yreka, which prospects exceedingly rich. They pounded out $40 last Friday in a hand mortar, and next day in a couple of hours some $10 more. They have an arastra about completed, and as soon as sufficient water is obtainable, will commence grinding out the rich quartz on hand. Mr. McCook, the enterprising Humbug creek quartz miner, is busy fixing up the quartz-mill at forks of Humbug, in which he will place the new stamps ordered from San Francisco. Osborne & Dee have men at work getting timbers, lumber and poles on the ground to open the Keeneenaw mine. There is every chance of their making a big strike, for, just opposite, was taken out a large amount of gold many years ago. On last Saturday, Messrs. Goodrich, Disen, Storey and Amos made a discovery of what appears to be a good quartz ledge 14 inches thick, in a gulch about three-fourths of a mile from the Anderson ranch. They propose to put an arastra on it, to prospect. They claim the rock will go from $100 to $1000 to the ton. This is the second or third good ledge they have discovered in that vicinity.

FROM KLAMATH RIVER.—Yreka *Journal*, April 5: From the Anderson grade can be seen three new buildings on the west side of the river; that of Mr. Chas. Jillson, on the summit above rancherie, near his hydraulic mines; that of Osborn and Dee on the Keneenaw mine at mouth of Printer gulch, and that of Mr. Wm. Jillson below the Pope ranch. This begins to look something like a boom for Klamath river. Pullen is putting in rock cribs. Waggonner & Freshour, Osborn & Dee, and Jillson commence this week or next. From Cottonwood creek to the mouth of Shasta river there will be not less than 50 men working in the mines in Klamath river. Deyson, one of the parties who was reported as finding a rich quartz ledge last week, is very much elated over his find and desires to sell or bond his ledge, guaranteeing that it will go from $50 to $500 to the ton. His reason for so doing, we understand, is lack of capital to open it.

San Bernardino.

THAT SILVER MINE.—*Times-Index*, April 6: This morning W. A. Evans of this city visited the *Times-Index* office to show the samples of ore and the assays made therefrom taken from the new, rich lode just discovered by him and his associates, who are Frank H. Evans, O. D. Gass and A. Preciado. The mine is in the mountains nine miles a little west of south of Bagdad, a station on the Atlantic & Pacific railroad, about 60 miles east of Daggett. The vein is very narrow on the surface, and as the vein goes down it widens out, a wash cuts the vein at one point and in the bottom of the wash the vein is three feet wide. This is about 30 feet below the adjoining surface. At four feet below the surface, the ore yields 2600 ounces of silver to the ton. In the bottom of the wash the ore goes 425 ounces to the ton, surface rock only being used. The character of this ore is the same as that found at Calico, but much richer and in wider veins. The owners have a ton of ore now out taken from the croppings, which will be shipped to the Selby Smelting Co. as soon as possible. Joe Craig and his brother Clark Craig, sons of the old pioneer assayer, Joseph Craig, leave to-morrow morning with assaying outfit and tools to open up their extension of the original mine, which is named the Silver Cornucopia. The owners of the original mine have a force now at work tunneling and opening up what promises to be the richest silver lead ever struck in the State. The vein has been traced for over two and a half miles, and the rock the entire distance appears to be about the same, although no assays have been made beyond the original mine.

Trinity.

COX BAR.—Trinity *Journal*, April 6: We received the following from T. C. Wright of Cox Bar in regard to matters in that place: T. B. Price began his summer work in his drift claim Wednesday with a full crew; the claim is in good shape to work and has plenty of good ground. He has at least three seasons' work of good pay dirt in sight and will undoubtedly make a good showing this summer. The Willshire hydraulic mine, owned by Bigelow, Jordan & Stackpole, is running with a good head of water and has good prospects considering the shortness of the season. C. J. Johnson's mine is also in fine shape and is paying good dividends right along. The dam at the Lower Trinity tunnel put in last summer by T. J. McWorthy has successfully stood every raise on the river.

Tuolumne.

BLACK OAK.—*Union Democrat*, March 30: The ten stamps at the Black Oak mill are pounding away merrily, and the company contemplates putting in five more. The admirable management of the mine has made it one of the most successful in the county. The new hoisting works are being pushed to completion.

AIR-COMPRESSOR.—During the past week there has been placed in operation on the Bonanza mine a Richman air compressor. It operates the engine, pump and hoisting works by compressed air instead of steam as heretofore used, and greatly facilitates the mining operations with considerable reduction of expense. With steam, it has been necessary to stop the pumping engine several hours in the day, so great was the heat in the lower workings; with air the mine is kept cool by a steady cold current of air flowing therein. The machine is a solid, compact, simple structure. The compressor in the Bonanza mine is operated by a 24-foot overshot water-wheel, erected by Mr. James Hamilton.

NEVADA.

Washoe District.

CROWN POINT.—Virginia *Enterprise*, April 6: Shipped to the Mexican mill during the week 912 tons 880 pounds of ore, of which 875 tons were milled, the average battery assay of which was $1.37 per ton.

HALE & NORCROSS.—On the 400 level are stoping ore of good quality from the south drift from west crosscut. The drift north from west crosscut No. 1 is advanced 25 feet and continues in fine ore, 25 feet being added since last report. On the 500 level have started a northwest crosscut 75 feet north of main west drift; this crosscut is now advanced 40 feet. The north and south upraises continue in excellent ore. On the 600 level are extracting the usual quantity of fine-grade ore from the several stopes. On the 700 level have started a south drif from the end of the main west drift. This drift is now advanced 25 feet, the last 15 feet being in good ore. Seventy-five feet north of this point started a new west crosscut from the main north lateral drift. This crosscut is now advanced 30 feet. The north upraise was advanced 15 feet and connected with the 600 level. This greatly benefits the ventilation of this part of the mine. During the week have hoisted 952 tons of ore; have shipped to the Nevada mill 958½ tons and have milled 802 tons. Average battery samples, $27. Shipped during the week bullion amounting to $16,030, and have $25,000 bullion on hand.

SAVAGE.—On the 400 level are stoping ore of fair quality from Nos. 1 and 2 southwest crosscuts. From the north drift on this level are extracting ore from the old stopes. On the 500 level the upraise from No. 3 west crosscut was extended 17 feet, and continues in low-grade quartz. From the south drift on this level are extracting ore from the old stopes, also from No. 3 east crosscut, 600 level. During the week hoisted 612 tons of ore and shipped to Rock Point mill 525 tons. Average battery assays $21.18. Have shipped $19,399.19 in bullion, and have bullion at the mill amounting to $15,000.

ALPHA AND EXCHEQUER.—On the 382 level the northwest crosscut is in 57 feet. Face in clay and porphyry. The northeast crosscut is in 54 feet. Face showing streaks of quartz, clay and a little water. On the 500 level the north lateral drift is in 413 feet; face in quartz and clay and the ground is very heavy, with a little water. The northwest crosscut is in 256 feet. The face is in hard blue porphyry.

CONFIDENCE.—The joint challenge and Confidence east crosscut No. 1 on the 1300 level is in 30 feet, 13 feet having been added during the week. The face shows vein material. East crosscut No. 2 on the same level is out 7 feet. Shipped during the week to the Brunswick mill for reduction 427 tons of ore, the average battery sample of which shows a value of $34.71 per ton.

OVERMAN.—Extracted 292 tons 1600 pounds of ore. Shipped to the Vivian mill 238 tons 1720 pounds of ore. Are stoping out ore at top of upraise from the east drift on the 226 level. The ore is of fair grade. Stope from winze from west crosscut No. 7 continues to yield the usual quantity of fair ore. Have done some repairs on Lambert winze.

ALTA.—The mill running steadily from ore on the 800 level and stopes above the 825 and 955 levels. Are upraising in fair milling ore on the 925 level in a body from 10 to 11 feet wide. The upraise on the 725 level is up 380 feet. Crosscutting will commence 30 feet further up to connect with the workings on the Keystone ledge.

SEG. BELCHER.—The west crosscut on the 1100 level is out 153 feet, having advanced 45 feet during the week. It has cut two stringers of quartz, which yielded fair assays, and the face is now in material of an encouraging nature.

CHALLENGE CON.—The work in this mine is jointly with the Confidence. During the week 22 tons of Challenge ore was shipped to the Brunswick mill, the average battery sample of which shows a value of $34.21 per ton.

CHOLLAR.—North drift 850 level is out 66 feet; face in very hard ground. North drift 750 level is out 117 feet; face in clay and porphyry. North drift 550 level is out 857 feet; face in low-grade quartz.

THERE are no new developments to report beyond progress in Justice, Baltimore, Silver Hill, New York, Bullion, Andes and Yellow Jacket, where fair prospecting work is being done.

SCORPION.—During the past week the west crosscut on the 350 level was advanced 16 feet, making its total distance 440 feet. The face of the drift continues in vein porphyry and clay.

POTOSI.—West raise 930 level, 400 feet south of the shaft, is up 27 feet; face in porphyry and low-grade quartz. West drift 650 level is out 29 feet; face in low-grade quartz.

CON. IMPERIAL.—Repairs to the main north lateral drift of the Con. Imperial mine being for the present completed, all work in this mine has been temporarily suspended.

BELCHER.—The 200 east crosscut advanced 42 feet during the week, making its total length 140 feet. The surface is in quartz and porphyry giving low assays.

Bristol District.

COPPER.—The Roe Bros. shipped from Bristol last week 24 tons of copper bullion, the product of the last run of their small furnace. The collapse of the copper syndicate will prevent further working in Bristol mines for copper until the market becomes more settled.

Jumbo District.

PANDORA.—Virginia *Chronicle*, April 3: The Pandora mine is yielding the usual amount of ore, showing an assay value of over $200 a ton in gold. Another batch of ore is being hauled to the arastras on the Carson river on the site of the Merrimac mill for crushing. The Wild Goose is also producing ore of even higher grade than the Pandora. Ore from the latter mine is crushed at Fisher's mill in Six-mile canyon.

Pioche District.

YUBA.—Since last mention of work here, a new vein of galena ore has been discovered, which is termed the "south contact." It lies west of the shaft and was first struck on the 11th level. A short crosscut from the 12th also cut the vein, where the ore is almost pure galena, from 6 to 12 inches in width, and assaying 100 to 150 ounces in silver. The vein is being developed on both levels. The crosscut from the 12th level running north to strike the Chief of the Hill and Burke ledges has progressed 140 feet. Small stringers of ore are encountered, though it is estimated that 100 feet or more must yet be run before cutting the ledges. During the past ten days teams have come in well, and 25 tons of ore have been shipped to the terminus.

TANK.—An iron tank of 600 gallons capacity, for hoisting water from the Raymond shaft, arrived last Sunday. It will be used to facilitate the first operations of the big pump in cleaning the sump. From 7500 to 8000 gallons per hour can be hoisted with it.

PUMP COLUMN.—The 40-foot timbers for use on

the pump column at the Raymond shaft have begun to arrive. Two of them make a load for the average team, and to see them freighted in this style is in contrast with the way Pritchard's fast freight teams brought in similar timbers years ago from Eureka, when one of the teams carried as much as a railroad train.

DISCHARGED.—Twelve men were discharged last Saturday night at the reduction works. The number employed there could not be advantageously worked. All the stone-work connected with the plant will be finished by contract, which has already been let to L. Syphus & Sons.

Tuscarora District.

BELLE ISLE.—*Times Reporter*, April 5: West crosscut 250-level, extended 10 feet, the face shows the same character of porphyry and is a little harder.

COMMONWEALTH.—100-foot level: North drift from No. 1 east crosscut, has been advanced 17 feet, face being in ore assaying $129 per ton. North drift from Queen line is showing high-grade ore, where the stull timbers are being put in. The main south drift is also yielding good ore 140 feet south of the shaft, where it is being stulled. North of the shaft, same level, No. 1 west crosscut has been advanced eight feet, and connected with the intermediate drift, cutting rich ore. West intermediate drift has been extended 11 feet. It does not show quite so well, the ore being a little mixed. 225-foot level: Intermediate drift from east lateral winze has been extended 11 feet south and 10 feet north, exposing very fine ore the entire distance. South drift from bottom of No. 1 winze has been advanced 8 feet; total, 23 feet; and north from same point, seven feet; total, 16 feet. The ore being developed by this drift is very high grade.

NEVADA QUEEN.—The Union mill was started Monday, the 1st, and is running nicely, the machinery all working well. The concentrator is also running steadily and doing good work. At the mine the east crosscut on the 450-foot level has been advanced 18 feet, passing through small seams of sulphurets and clay, looking very favorable for ore. The stopes are improved since last report, and are yielding some good milling ore. Average assay of ore hoisted $182 per ton. Everything around the mine is working well.

NORTH BELLE ISLE.—North drift, 500-foot level, extended seven feet. The water is now under control and the ventilation good. The intermediate stopes are looking fair. The stopes above the 300-foot level are opening out wide and are looking very fine. The stopes on the 150-foot level turning out some high-grade ore. The Union mill started Monday on Nevada Queen and North Belle Isle ore and everything is running smoothly.

GRAND PRIZE.—East drift, 300-foot level, extended 13 feet; face showing 18 inches of good ore. 400-foot level: East drift from north crosscut extended 12 feet. West drift from same crosscut 21 feet and an east drift No. 2 from north crosscut started and is in 17 feet, ore streak one foot wide and high grade. Face of south drift advanced 14 feet. East crosscut 17 feet through a more favorable looking formation.

NAVAJO.—The stopes are looking fair throughout the mine and the usual quantity of ore has been sent to the mill.

ARIZONA.

HASSAYAMPA DISTRICT.—Prescott *Courier*, April 5: The Blue Dick, Hassayampa district, continues to favor John McDonald and Tom Brown with plenty of rich ore. They shipped yesterday 23,170 lbs. of ore worth, per ton, silver, $427; gold, $1800. This shipment contained six per cent copper. A carload of second-class ore, shipped by them last week, sampled 235 ounces of silver and $12 gold to the ton. For the 11 months previous to this, these worthy miners mined, packed and shipped ore worth $9000. They have in stopes and on dumps 2000 tons of ore worth $30 a ton.

CONGRESS.—Several wagon-loads of rich gold-bearing sulphuret ore arrived yesterday from the Congress mine. A 20-stamp mill will soon be up and running at the mine. About 100 men are employed in and around mine and mill. Harlan & Barrington are crushing ore from the Howard mine in their mill, 12 miles south of Prescott. Mr. Dunkle has struck it rich in the Scotch Lassie. Tom Bowman of Lynx creek was at the Pioneer hotel yesterday, and stated that 50 or 60 men were making good wages in the placers. T. W. Otto had, yesterday, 16 ounces of nice gold, besides a 2½-ounce piece which Peter Brady recently found above the Lynx creek hydraulics. The tapping of old workings in the Senator mine caused a big flow of water, which rose 40 feet in the new shaft.

DAKOTA.

AFRAID OF DAKOTA TIN.—Deadwood *Pioneer*, April 6: The project in London to form a combination of tinplate manufacturers to control the price and amount of production received a check when on the point of consummation, by the receipt of private reports concerning tin mines in Dakota. While many of those interested in the proposed combination look at stories of their richness as exaggerated or altogether untrue, prudence demands further investigation. One Jewish capitalist is known to have invested heavily in the Dakota fields, on the strength of reports sent to him by a relative in America, and the amount of money he has at stake is enormous. The mines of Cornwall are worked with ever-increasing difficulty and expense. The Banca deposits are the only others of known value, and the product of this distant Malayan district is uncertain. South Wales and Worcestershire tinplate makers look with alarm at the possibility of having to contend with factories established in the heart of a country which is by far their best customer. It may be looked upon as certain that if the situation proves to be as critical for them as it now seems, they will make desperate efforts to gain control of the Dakota mines at any cost.

IDAHO.

ROCKY BAR.—Wood River *Times*, April 3: E. C. Coffin returned to-day from Rocky Bar, where he went to complete arrangements to resume operations with the Alturas Fast Freight Line between Hailey and the Bar. He says that it is rather quiet there just now; but that in two or three weeks the Alturas Limited will resume operations on a larger scale than ever. This company discharged most of its employes some time ago, pending reorganization. This is progressing, and will doubtless be completed within a month.

RED ELEPHANT.—Last Thursday afternoon a new ore body was cut into in the upraise about 700 feet from the east end-line of the Red Elephant claim. This was in entirely new ground, and higher than there have heretofore been any workings at that end of the claim. Only 10 men are employed at the Red Elephant group at present, the force having been greatly reduced since Col. Bryan, the manager and third owner, left for the East about three weeks ago to purchase hoisting and concentrating machinery.

THE NARROW GAUGES.—Supt. Wilson of the Narrow Gauge group of mines intends to go to work at once to put a hoisting engine and pump in position near the end-line of the Narrow Gauge No. 2 mine, preparatory to sinking a shaft down about 115 feet for the present.

PINE GROVE is also dull at present; but the companies interested there are expected to resume operations soon, when the camp will, it is hoped, become permanent.

MONTANA.

HELENA DISTRICT.—*Montana Mining Review*, April 6: A flying trip to the Helena district a few days since revealed the fact that mining operations in that locality are assuming proportions that tend to place the district in the front rank of Montana's great mineral-producing belts. On every side signs of activity are manifest, and not only is the indefatigable "prospector" abroad pursuing his search for new discoveries, but many claims are being put in readiness to be extensively developed. Of late, the district has attracted more or less attention from capitalists and mining men from abroad. Probably the most important transaction of the past week relative to the Helena district was the bonding of the West Grass Valley mine by Messrs. Hauser, Holter et al., the bond to expire in June. This is a very promising property, and has produced some very fine ore, showing improvement as development progressed. The owners, Messrs. Brennan, Coffee and Nevill, have shipped considerable ore from this mine with very satisfactory results. It is said that the stockholders of the Christmas Gift are trying to perfect such arrangements as will enable them to develop their property, which has produced some of the richest ore in the district, and has only lain dormant for the past few years because of a lack of harmony among the stockholders. The Bonanza Co. have let the contract for 50 feet of sinking on the Little Bonanza lode, and arrangements are now going ahead to have everything in readiness to commence putting the shaft down in the course of the next few days. The Hard Cash is looking well, and a few days since 11 tons of first-class ore were shipped from the mine. We hear talk to the effect that the well-known Helena mine will be worked and brought to the front this season.

NEW MEXICO.

RUBY.—*Western Liberal*, April 5: The Ruby Co. of Gold Hill made a shipment of some of its ruby silver ore this week. It is reported that this summer two more large companies will go into the Pinos Altos camp. The Hachita Mining Co. is patenting the Copper King, Center and Mammoth mines in the Apache district. During March about $23,000 in gold bullion and nearly the same value in silver bullion was shipped from Silver City through Wells, Fargo & Co. Robert Williams shipped a carload of ore from his Ocean Wave mine to the International smelter at El Paso this week, and the smelter has contracted to take all he will ship. The ore runs from 50 to 60 per cent lead and good pay in silver. There seems to be quite a demand just now for lead ore. The Santa Fe Copper Co. last week issued the following order: To the foremen of the mines and smelters of the Santa Fe Copper Co.: You are hereby notified that you will be held personally responsible not to employ or keep in employment any man who gets drunk or is in the habit of frequenting gambling-houses. Such employes, whether miners, laborers, foremen, teamsters, etc., must be discharged at once, and will not be employed again by the company. This is done for the benefit of the camp and the employes generally.

UTAH.

REVIEW.—Salt Lake *Tribune*, April 6: Three months of the current year have now passed, with bullion receipts as follows in this city, excluding all ores:

January	$177 442 83
February	181,249 63
March	238 226 00
Total	$597,918 46

A number of producing operations are not reported herein, which do not make current reports. The week has been a dull one, so far as new enterprises are concerned, in the precious metals. But the bullion output was high for the week, and the movement of ore fair. For the week ending April 3d, inclusive, the receipts in this city aggregated $168,852, of which $111,967 was in bullion and $56,885 was in ore. The week previous the receipts were of the value of $93,468 in the aggregate, of which $53,768 was in ore and $39,700 was in bullion. The product of the Ontario for the week was from ore sales, 326,-926.13; bullion, 21,309.68 fine ounces; an approximate total of $48,235.81. The March returns are not all in, so that the statement for that month is not available. The total number of dividends paid by the Ontario, including that of March, 1889, is 154, amounting to $9,950,000. The Daly output for the week was of ore sold, $12,252.30; bullion, $10,267.-40; a total, approximately, of $22,519 70. The total dividends paid by the Daly number 25, and amount to $975,000, including that for March. The Horn Silver is doing very fairly in its preliminary and development work. It ships some ore, and has a reserve fund on hand sufficient to meet all ordinary and some extraordinary expenses; and that fund is growing. Fine bar receipts in this city were valued at $76,662 for the week; base bullion, $20,755. The Hanauer smelter produced bullion during the week valued at $14,200. Ore receipts in this city for the week were of the value of $37,260 by Wells, Fargo & Co., and $19,625 by McCornick & Co.

MARKET REPORTS.

Local Market.

SAN FRANCISCO, April 11, 1889.

General trade continues steady, with buyers evidently pursuing a conservative course. Iron-workers still report "slow business." Much of this, no doubt, is due to the uncertainty regarding the future price of lumber. Many contractors do not wish to make bids on buildings and other work when both iron and wood are used, fearing that advances will be made in the price of lumber, which may entail heavy losses to them. The local money market is dull and inactive, with more funds offering than can be absorbed. The past week loans have been made on gilt-edged security at the rate of from 4 to 5 per cent a year. On realty there were placed nearly $300,000 at from 6 to 7 per cent a year. The mercantile community report collections fairly easy. The favorable outlook for large crops and the heavy deposit of snow in the mountain ranges are important factors in promoting a very hopeful confidential feeling. Exchanges on the East are easier.

The receipts of treasure by sea the past week aggregated $13,205.

In the month of March the shipments of treasure from this port aggregated in fine silver, $683,700; gold coin, $914,312; silver coin, $52,635; Mexican dollars, 457,635; currency, $491,301.

The amounts and descriptions of specie shipped from San Francisco in the first three months of the year compare as follows:

	1888.	1889.
Silver bars	$2,185,450	$2,082,200
Mexican dollars	928 620	1,507,078
South American dollars	2,208	41,131
Gold coin	1,100,228	2,910,017
Silver coin	7,300	42,450
Gold dust	160	670
Currency	249 980	531,301
Totals	$4,473,946	$7,114.847

The last steamer sailing for China took out in Mexican dollars $312,888; gold coin, $6425; gold dust, $70; silver bullion, $209,000. Total, $528,383.

SILVER—The market weakened off a fraction, then recovered, but shaded off to 92½c on yesterday, at which price our market is quoted weak at the close. London cables came through to-day quoting 42¾d, while New York was quoted at 92⅜c against press telegrams received yesterday of 92½c. The supply of bullion in our market is still very light, yet owing to the dull, inactive market, prices are barely sustained at New York quotations. The shipments to China are small compared to that made in Mexican dollars. The easier rates for exchange on the Eastern cities are against silver locally. Cablegrams report that the Indian Council bills have been allotted quite cheap, which combined with an easy money market in India, is against silver.

MEXICAN DOLLARS—The demand continues fairly good, absorbing about all received, at from 72¾ to 73¼c, according to quality. The price, contrary to former seasons, has not fluctuated with that of silver bullion.

QUICKSILVER—The market is quiet, but firm. Foreign advices indicate an improvement later on in the market. Receipts the past week were as follows: T. Bell & Co., 70 flasks; Parrott & Co., 40; W. B. Bradford, 34; Knox & Osbourne, 16; Haas Bros., 71. Total, 231 flasks.

COPPER—The market is quiet, pending final settlement of the affairs of the late French syndicate. Cablegrams encourage the belief that a settlement has been arrived at satisfactory to all interests, but the details are not, at this writing, obtainable, and until authoritative advices are received, conjectures are useless.

LEAD—The market is without change. The local demand is fairly active, but this usually obtains during the canning season.

TIN—The arrival Wednesday of 45,868 boxes tinplate has relieved the market, bringing in sellers for spot at from $5 to $5.25. At the decline there is more business. The shipments by water the past week were 164,162 lbs. of tinplate to Victoria, B. C. Foreign advices indicate that the syndicate which was reported to be forming will probably come to nothing, and the project be abandoned.

PIG IRON—The market is very quiet, but the tone is strong under firm holding, owing to advancing markets abroad. Consumers continue to pursue a conservative course, for they only buy in a hand-to-mouth way. The Puget Sound Iron Co., at Irondale, contemplates building a rolling-mill. The Moss Iron and Steel Works on Puget Sound will soon be ready for work.

BORAX—The market is quiet but steady. Receipts the past week aggregated 1664 ctls., while the shipments via Victoria, B. C., were as follows: 20,164 lbs. to Chicago, and 24,576 to Cedar Rapids, Iowa.

LIME—Receipts the past week aggregated 4,-468 bbls. The demand is good.

COAL—Imports the past week were as follows: From Tacoma, 5900 tons; Australia, 3959; Seattle, 7027; Coos bay, 650; Departure bay, 3838; Nanaimo, 815. Total, 22,189. For Cumberland the market is strong, owing to light stock and high freights. In English, the market is steady, but for Australian and coast, buyers are favored, or, in other words, the market is easy.

Eastern Metal Markets.

By Telegraph.

NEW YORK, April 11, 1889.—The following are the closing prices the past week:

	Silver in London.	Silver in New York.	Copper.	Lead.	Tin.
Thursday	42¼	92¼	$14 50	$3 67	$21 25
Friday	42¼	92⅜	14 25	3 72½	21 19
Saturday	42¼	92⅜	14 25	3 67½	21 05
Monday	42 5-16	92⅜	14 50	3 65	20 95
Tuesday	42 5-16	92⅜	14 25	3 65	20 90
Wednesday	42⅜	92⅝	14 50	3 65	20 86

NEW YORK, April 11.—Copper remains without much actual business. Speculators seem banded to hold up prices until a more favorable understanding in relation to the winding up of the deal across the ocean can be obtained. Lake ingot was offered at 15½c for spot, or delivery in a month at 15c; May, 13½c; June and July, 13c, sellers option for the rest of the year; merchandise brands, 12@12¾c; early delivery. May to close of the year, from 10 4-5 down to 9½c. Pig lead, after easing off, closed steadier. Tin closed firmer, with the tendency upward. Pig iron has a firmer tone, due to the large consumption and light supplies.

Mining Share Market.

Trading in mining stocks the past week was more active, with Mexican and Union the leaders, under confirmed reports of an improvement in the former and important work going on in the latter. In the MINING AND SCIENTIFIC PRESS of December 22d it was stated that mention was made that when crosscuts were run in Mexican and Union from the 1465-foot Ophir drift running north, it was expected that ore bodies of value would be run into. In the Mexican this has been verified, and in Union, mining engineers are confident of still better results, provided the heat does not force the company to make an upraise to the 1300-foot level of Union for air connection. About ten years ago an important ore development was made in the 1300-foot level in Union, a winze sunk on the ore body, but work was discontinued, although the face of the winze is said to have been in rich ore. The news from Hale and Norcross is of an important character. The assay value of the ore is steadily increasing, as is the quantity of ore being milled. The work in the mine toward the west is very important. In Crown Point, preparations are being made to resume work in the crosscuts from the west drift on the 400-foot level. Advices from Mexican report the ore to be improving in value and of more importance than before claimed. From the other mines being worked on the Comstock, the news continues of an encouraging character, while preparatory work is either under way or will be soon inaugurated to resume explorations. From the Tuscaroras the news does not vary materially from that heretofore given. The same remarks are applicable to the Bodie and Quijotoa districts.

The past week the following assessments were levied: Occidental, 50 cents, Bulwer, 25 cents, and Found Treasure 12½ cents.

The ore yield of the Comstock mines during the week ended April 8th aggregated 6672 tons, as follows: Consolidated California and Virginia, 2896 tons, assay value of $30.10; Gould and Curry, 74 tons, assay value, $19.75; Best and Belcher, 40 tons, assay value, $38.50; Savage, 525 tons, assay value, $19 50; Hale and Norcross, 958 tons, assaying $30; Confidence, 497 tons, assay value, $34.21; Challenge, 22 tons, assay value, $34.21; Crown Point, 912 tons, assay value, $19.37; Overman, 248 tons; Alta and Justice, 500 tons. The bullion yield of the above was about $155,000.

An Electric Railway for Portland.

The Willamette Bridge Co. have accepted the Sprague Co.'s proposal to equip the Albina division of their street railway system in Portland, Oregon. The equipment is to include 1½ miles of track, five cars, 15-horse motors and a drawbridge.

A letter to Mr. J. L. Jayne, the agent of the company in this city, relative to this contract, is as follows:

PACIFIC BRIDGE COMPANY,
SAN FRANCISCO, April 2 1889.

J. L. Jayne, Esq., San Francisco—DEAR SIR: In answer to your inquiry of this date in regard to building an electric line at East Portland of the Sprague Electric Railway System, I would say that after our inquiries in the East in regard to your system, we have concluded to adopt it on our Portland and Albina line, believing it to be the best electrical railway system in use, and believing it to be the cheapest street railway system now in use, taking into consideration the advantages it has over steam, horse or cable railways.

Messrs. Swigert and Campbell, who run our Portland railroad, and are half-owners of the same, have made a careful study also of your system, and it was through them that I was induced to investigate your system, and both agree with me in adopting it.

We shall commence work on it at once, and expect to complete it in three months. Very respectfully yours,

R. W. GORRILL,
President Pacific Bridge Co.

Bullion Shipments.

We quote shipments since our last, and shall be pleased to receive further reports:

Hale and Norcross, April 6, $16,030; Savage, 6, $19,736; Cons. California and Virginia, 6, $112,127; Gould and Curry, 6, $3381; Clip Consolidated, 6, $10,000; Savage, 8, $8200; Peerless, 8, $10,420; Crown Point, 6, $10,321; Mt. Diablo, 4, $7830—total for March, $36,348; Hanauer, 6, $1865; Alice, 6, $34,160; Bluebird, 6, $13,840; Cons. California and Virginia, 10, $76,404—total for March, $338,456; Mt. Diablo, 10, $8188; West Comstock, 10, $3000; Justice, 8, $3325; Lexington, 6, $26 224; Moulton, 6, $7888; Alice, 6, $33.000; Butte and Boston, 6, $23,920; Hanauer, 3, $4600; 6, $2500; Alice, 6, $34,160.

THE trouble between the colored coal miners imported into Roslyn by the Northern Pacific Company and the whites is not ended.

JAMES LEFFEL'S Mining Turbine Water Wheel.

These Wheels are designed for all purposes where limited quantities of water and high heads are utilized, and are guaranteed to give more power with less water than any other wheel made. Being placed on horizontal shaft, the power is transmitted direct to shafting by belts, dispensing with gearing.

Estimates furnished on application for wheels specially built and adapted in capacity to suit any particular case.

Further information can be obtained of this form of construction, as well as the ordinary Vertical Turbines for Wooden Penstocks and in Iron Globe Cases, free of cost, by applying to the manufacturers.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, $3.00 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber, please show the paper to others.

THE Cons. California and Virginia M. Co. worked last month 11,783 tons of ore. Total bullion produced—Gold, $152,300.95; silver, $186,155.07; total, $338,456.02. Average yield in bullion per ton, gold, $12.92; silver, $15.79; total, $28.71. Average assay value of the ore per ton, $33.89.

The Death of D. K. Regar.

S'owly and solemnly, to the dirgeful strains of the Elkhorn Brass Band, a long procession moved off to follow the remains of D. K. Regar to their last resting-place. Mr. Regar was well known in mining circles in Nevada, California, New Mexico and Arizona. He was foreman of the Elkhorn Mining Co.'s property, of which Mr. J. W. Ponder is General Superintendent, and had been with him a number of years. On the morning of the 20th of March a large piece of shale fell upon him from the hanging-wall, breaking six of his ribs and making a compound fracture of his left leg above the ankle. All that care and medical skill could do was done for him, but he rapidly sank under his severe injuries and expired at 4 P. M. on the 21st. The large number of mourners who followed in the long funeral pilgrimage of 18 miles attest more strongly than words to the esteem in which the deceased was held by the community. He was buried at Boulder, in the cemetery of the I. O. O. F., under the auspices of that order, of which he was a member. *Requiescat in pace.*

California, Arizona and New Mexico papers please copy.

Every Miner His Own Assayer.

A chemical for testing and ascertaining the value of all kinds of ore, by which every miner and prospector can make his own assays, anywhere in the mountains, at a cost of a little over 5 cents and in a few minutes' time. No apparatus or dangerous acid needed; a dry powder, which may be carried in the pocket. This, mixed with the ore and a little water in a teacup, produces an electric current, which separates the silver from the ore instantly, no matter how refractory. Try it; you will be delighted Will save you many dollars for assaying. Package sufficient for 30 tests, with full directions, by mail to any address on receipt of $2; 6 packages for $10. Address, Prof. J. Herman, P. O. Box 1845, San Francisco, Cal.

THE CALIFORNIA CONSOLIDATED Gold Mining Company, Sierra City, Cal., A. Schubert, President; Alvin Fischer, Secretary; A. Leller, Superintendent. Divided into 300,000 shares at $1 each. Property comprises two locations. Ore assays $7 per ton, average. Coarse gold, solid rock; vein from 15 inches to 2 feet wide. Tunnel No. 1 in 120 feet, and prospects well. No. 2 just begun. Stockholders: Alvin Fischer, A. Schubert, Gus Fischer, F. L. Fischer, Anton Fischer, Fred Fischer. For information concerning stock, etc., apply to F. L. Fischer, Sierra City.

THE BUFFALO CONSOLIDATED GOLD Mining Company, Sierra City, Cal., Ernest Busch, Superintendent. Stock divided into 600,000 shares at $1 per share. The property comprises 5 locations. Ore finely decomposed, carries coarse gold. Size of ledge: Tunnel No 1, 32 ft.; No. 2, 94 ft.; No. 3, 10 ft. Fine black decomposed rock interspersed with white quartz. New 10-stamp mill run by a Pelton Wheel, blacksmith shop and boarding house. Stockholders: Ernest Busch, Hugh Murray, Frank Cook, J. G. Lee, Henry Carpenter. For further information apply to Ernest Busch, Sup't, or Hugh Murray, Sec'y.

ASSESSMENT NOTICE.

Gray Eagle Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Placer County, California.

NOTICE is hereby given, that at a meeting of the Board of Directors, held on the 19th day of March 1889, an assessment, No. 12, of Five Cents per share was levied upon the capital stock of the Corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, Room 9, No. 327 Pine Street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 23d day of April, 1889, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on Tuesday, the 14th day of May, 1889, to pay the delinquent assessment, together with the costs of advertising and expenses of sale. By order of the Board of Directors.

O. H. BOGART, Secretary.

OFFICE—No. 327 Pine Street, Room 9 S. F. Stock Exchange Building, San Francisco, Cal.

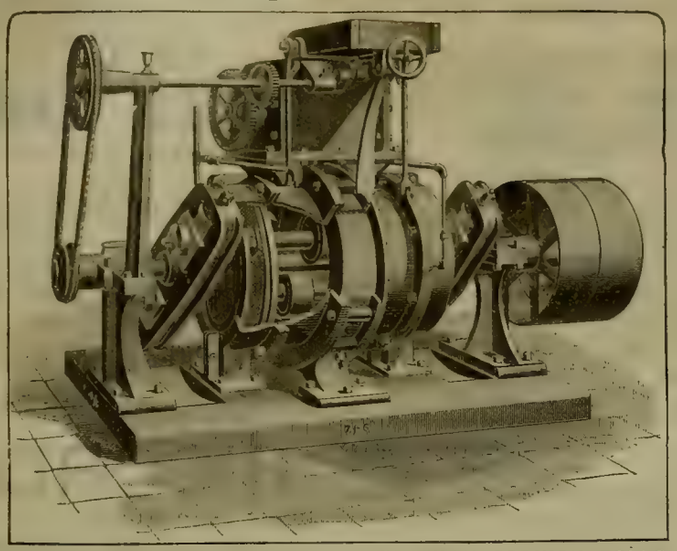
FRISBEE WET MILL.

This Mill, with a weight of less than 9000 pounds, has a capacity of three tons per hour of hard quartz to 40 mesh; has been thoroughly tested; we guarantee its work as represented, and we will give long time trial.



IT HAS NO MORE WEARING PARTS THAN CORNISH ROLLS,

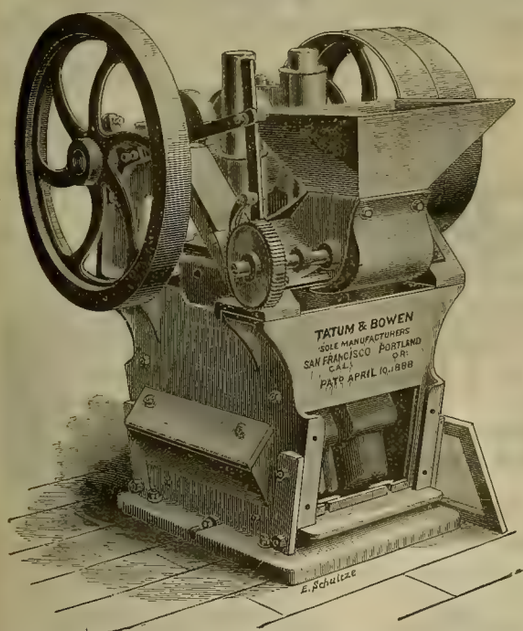
And renewals will not cost over one-half as much as for stamps. Will run empty, or with small amount of ore without injury. The attention of parties having Cement Gravel is called to this Mill, as it will run 100 tons per day to No. 8 mesh; 30 to 35 H. P.

OUR DRY MILLS are the most economical ever built, and are extensively used with record of several years. No grinding in pans. Mill finishes to any fineness desired.

FRISBEE-LUCOP MILL COMPANY,

GIDEON FRISBEE, Manager, - - - 32 First Street, San Francisco.

HOOKER & LAWRENCE, Gen'l Ag'ts, 145 Broadway, New York.



—THE—

PERFECTED DOUBLE Economic Quartz Mill.

Attached to each Mill is an effective

Automatic Ore Feeder.

THE CRUSHING is done by the rapid rocking movement in OPPOSITE DIRECTIONS of two heavy castings, the bottoms of which are slightly circular in form, and each provided with four shoes.

The Mill is a closer Gold-Saver and catches a larger percentage of the Clean-up in the Battery than any other Mill.

It costs less, in proportion to what it will do, than any other mill. There are no working parts to buy for it, no matter how long it is used, except shoes and dies. Capacity of Mill, 6 to 10 tons per day. Weight of Mill, complete, 6400 pounds.

We manufacture, to go with the Mill, an

IMPROVED ROCK BREAKER.

Power required for Mill and Rock Breaker, 6 H. P. SEND FOR CIRCULAR. Address:

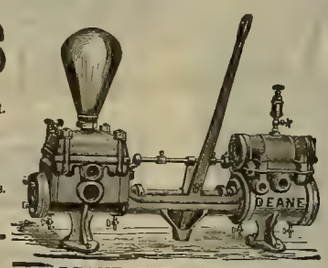
TUSTIN'S PULVERIZER.

—MANUFACTURERS OF—
MARINE ENGINES AND BOILERS.—Propeller Engines, either High Pressure or Compound, Stern or Side-wheel Engines.
MINING MACHINERY.—Hoisting Engines and Works, Cages, Ore Buckets, Ore Cars, Pumping Engines and Pumps, Water Buckets, Pump Columns, Air Compressors, Air Receivers, Air Pipes.
MILL MACHINERY.—Batteries for Dry or Wet Crushing, Amalgamating Pans, Settlers, Furnaces, Retorts, Concentrators, Ore Feeders, Rock Breakers, Furnaces for Reducing Ores, Water Jackets, etc.
MISCELLANEOUS MACHINERY.—Flour Mill Machinery, Saw Mill Engines and Boilers, Dredging Machinery, Powder Mill Machinery, Water Wheels.

Tustin's Pulverizer
WORKS ORE WET OR DRY.

ENGINES AND BOILERS
OF ALL KINDS,
Either for use on Steamboats or for use on Land.
Water Pipe, Pump or Air Columns, Fish Tanks for Salmon Canneries
OF EVERY DESCRIPTION.
Boiler Repairs Promptly attended to and at very moderate rates.
AGENTS FOR THE PACIFIC COAST FOR THE
Deane Steam Pump.
SPECIALTIES:
Corliss Engines and Tustin Ore Pulverizers.
Agents and Manufacturers of the Llewellyn Feed Water Purifier and Heater.



DEANE STEAM PUMP.

THE GIANT POWDER COMPANY
Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as
The Safest and Strongest High Explosives in the Market.
GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.
NOBEL'S EXPLOSIVE GELATINE," which contains **94 per cent of Nitro-Glycerine,** and **GELATINE-DYNAMITE, Stronger than Dynamite** and even Safer in Handling.
JUDSON POWDER IMPROVED.
FOR RAILROADS AND LAND CLEARING. Is from three to four times stronger than ordinary Blasting Powder, and is used by all the Railroads and Gravel Claims, as it breaks more ground, pulverizes better and saves time and money. It is as dry as the ordinary Blasting Powder and runs as freely.
BANDMANN, NIELSEN & CO.,
CAPS and FUSE for Sale GENERAL AGENTS, SAN FRANCISCO CAL.

QUARTZ SCREENS
A specialty. Round, slot or burred slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.
Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

COAL MINES OF THE WESTERN COAST.
A few copies of this work, the only one ever published treating of Pacific Coast Coal Mining, have been obtained, and are for sale at this office for $2.50 per copy. It was written by W. A. Goodyear, Mining and Civil Engineer, formerly of the California State Geological Survey.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 38 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

THE GATES CRUSHER

Is beyond all question the most important improvement that has ever been made in this class of mining machinery. It will do more than twice the work with a given amount of wear than any other Crusher made, besides crushing so much finer that for mining uses, the capacity of the mill is greatly increased. It has the same relative superiority for macadamizing purposes, affording the cheapest and most reliable machine for this use.

54-INCH BY 16 FEET STEEL BOILERS IN 2 SHEETS.

STEAM USERS, ATTENTION!

The engraving represents our standard 54 in. x 16 ft. Boiler. These boilers are made of homogeneous STEEL, and the shell, as shown, being in TWO PIECES, the advantage of this will be readily appreciated by steam users.

There are NO SEAMS in the fire to leak, nor loose rivets to contend with, caused by the continual expansion and contraction of the plate on account of the unequal distribution of the heat under the boiler, the bottom presenting a smooth, even surface which can be easily cleaned. We place a manhole at the back end above the tubes, and one in the front end under the tubes.

The FRONT MANHOLE gives free access to the sheet over the fire, THE VITAL PART OF EVERY BOILER. This point is often overlooked by purchasers, and boilers are supplied with a small hand hole, and the remaining space filled with tubes which allows absolutely no access for cleaning, and in a short time tubes and sediment are one solid mass, and instead of gain in efficiency by a few feet of tube surface, the result is a positive loss.

SPECIFICATION OF BOILER AND FIXTURES:

1 Boiler, 54 inches diameter by 16 feet, with 46 3½ inch tubes; Shell, 5 16; Heads, 7-16.
1 Steam Drum, 36 inches diameter by 72 inches long.
1 Breeching.
1 Smokestack, 30 inches by 60 feet, Nos. 12 and 14 Iron.
300 feet galvanized strand for Guys.
1 C. I. Front, complete.
1 Foundation Plate for front.
1 Set Grate Bars for coal or wood.
1 Back Bar Bearer.
1 Ash Cleaning Door and Frame.
1 Back Arch Plate.
1 Set Binder Braces and Bolts for Brickwork.
1 Stand for back end of Boiler.
1 Steam Gauge and Syphon.
1 Glass Water Gauge, complete, with column and 3 Gauge Cocks.
1 Safety Valve.
1 Stop Valve.
1 Feed Valve.
1 Blow-off Valve.
1 Check Valve.

These Boilers are tested to 150 pounds hydrostatic pressure and are intended for a working pressure of 100 pounds. Total weight of Boiler and fixtures, 17,000 pounds.

☞ BOILERS ON HAND READY FOR SHIPMENT. ☞ SEND FOR CIRCULARS.

California Salt.

The most important mineral industry in Alameda county is the recovery of salt from the waters of San Francisco bay. This business is carried on extensively upon the east shore of the bay, in the neighborhood of Alvarado and Mt. Eden. At the former place Messrs. Plummer, Barton, Quigley and others have their works; at Mt. Eden are the works of P. Marsicano and the Union Pacific. Two methods are employed in Alameda county for the recovery of salt from sea-water. One is by complete natural evaporation and gathering the residue; the other by allowing tanks of sea-water to evaporate until a saturated solution is obtained, from which the salt is recovered as it crystallizes.

The first process is in use in the salt-ponds of the Messrs. Quigley of Alvarado. At these works a pond covering 400 acres and surrounded by a levee, is filled with sea-water at spring tide. This pond is divided into tanks. There are three tanks side by side, covering an area of 400 acres. As the density of the water in the tanks increases by evaporation, it is pumped by windmills from the two outside tanks to the center one until it is filled with strong brine. This brine is then pumped into a reservoir of 30 to 40 acres in extent, which is filled to a depth of 12 to 13 inches.

Here the density of the liquid rapidly increases, and the salt commences to crystallize. When a crust one and a half inches in thickness has formed upon the floor of the pond, the salt is scraped up. After gathering the salt, whatever mother liquor (bittern) remains is run off, no effort being made to recover any of the elements it may contain. The best and whitest salt is obtained in warm, windy weather, the wind forming ripples in the solution, which wash the rapidly forming crystals. In still, hot weather the salt has a yellow tinge. It takes about three years for a pond to get into a suitable condition for the production of salt. In that time a peculiar "skin" grows over the bottom, this protecting the solution from contamination by earthy matter. These works have been running for twenty years. Their output has been from 2500 to 3000 tons per annum. The second process is in use at the California and Union Pacific Salt Works, in the vicinity of Mt. Eden.

SALT POND AT ALVARADO.

The works of the California Salt Company are situated about half a mile southwest from Mt. Eden railroad depot. The plant consists of 50 salt ponds, which are arranged in "schools" (rows), together with several large reservoirs, one of which is three miles in circumference, the whole covering 2000 acres of land. The sea-water is let into the larger reservoirs, and from there is pumped by windmill into the smaller ponds, and from one pond into another, each pond increasing in the density of its solution. When a saturated solution has been obtained the salt crystallizes upon the surface; it then falls to the bottom of the liquid, where it accumulates. When it has collected to a depth of three or four inches, it is raked out and piled on platforms to dry. The crude material thus obtained is shipped from these works to San Francisco, where it is manufactured into the finer grades of salt by the American Salt Co. In their works the salt is placed in galvanized iron driers, heated by steam, each drier having a capacity of 22 tons per day. When thoroughly dried it is ground in burr-mills to various degrees of fineness, for dairy and household use. The capacity of the California Salt Works at Mt. Eden is 15,000 tons per annum; that of the mills of the American Salt Co. in San Francisco 1200 tons per month. The cuts show a salt pond at Alvarado and the grounds of the California Salt Works. For these and for the information herein we are indebted to the State Mining Bureau.

CALIFORNIA SALT WORKS, ALVARADO, CAL.

THE COPPER CORNER.—It is learned through a private letter from Paris that the American representatives at the Copper Conference desire to fix the price at £40 to £45 per ton. The Rio Tinto people want it fixed at £35, while the bankers interested desire it placed at £50. There is some talk of reconstructing the Societe des Metaux with Secretan as manager. Secretan attributes the collapse of the syndicate to the bankers, who insisted upon a high price instead of allowing a steady rise. The letter intimates that the Calumet and Hecla may make the price of copper, without regard to the Frenchmen, by combining with the Anaconda and Tamarack, but does not want to force the suspension of the production of other Lake Superior mines.

Displacing a Stamp-Mill.

In Old Diggings, nine miles north of Redding, on the east side of the Sacramento river, in Shasta county, is the Texas and Georgia mine, consisting of two claims bearing these respective names. The mine has prospected well and is turning out a lot of good ore.

Mr. Fleming ran arastras on the claim for three years and then sold to Hart & Day, who put up a five-stamp mill, getting as returns from $8 to $15 per ton from the rock. The mill burned down and Hart sold out, but Day not being a miner, the original owner, Fleming, took the mine back and Hart joined him. These two then commenced taking out ore, sorting it and shipping it to the Selby Lead Works, though the mill had in the meantime been rebuilt. They have shipped about seven or eight carloads of sorted rock, leaving about 450 tons of the refuse or low-grade ore. About one-tenth of all taken out was shipped.

Lately they have displaced the stamp-mill for a Dodge rock-breaker and pulverizer, which work very finely on this ore. After shipping the selected ore, the balance yields about $10 a ton in the Dodge machines. They obtain as much from the ore now, after the "cream" of it has been shipped, as they did out of it all under the mill system. One of the owners, who was recently in the city, gives us this information, and says that as far as tested the rock-breaker and pulverizer together take much less power and fuel than the stamp-mill itself did.

CORRESPONDENCE.

We admit, unindorsed, opinions of correspondents.—EDS

Tuolumne Mines.

EDITORS PRESS:—The Golden Gate mine is situated about one mile south of Sonora, and on the east of Woods Creek. The vein is large in size—from 3 to 12 feet thick. The quartz generally is of a grayish-blue color, lined by ribbons of arsenical pyrites; besides, the same base metal permeates the whole mass of rock, yielding about 3 to 3½ per cent of high-grade sulphurets when concentrated. The formation is magnesian slate, heavy mineralized, of which is the hanging-wall, with a small gouge under it.

The foot-wall is magnesian diorite dyke. The vein between the walls will average four feet, and appears to grow richer as depth is attained, being more solid and compact and gaining in percentage of sulphurets. I find assays made by Messrs. Riotte & Luckhardt, Falkenau & Reese and other responsible metallurgists, ranging from $573.30, $733.28, $1012.72, $1020.69, $8300.47. The latter is exceedingly high grade, far above average, but by careful treatment and close concentration of the finer grade of sulphurets, they being the richest, of a dark gray-steel color, I consider $1000 per ton should be realized on an average.

The vein cuts the slate at an angle of 15° to 20°, and this is the cause of getting such very high-grade metal, such being found where crossings strike the vein matter. In my experience where veins conform and run with the slates the yield of gold will be more regular, but certainly not so rich. These sulphurets yield easily to the chlorination process. With economy in the treatment and management generally, a grand margin of profit must result.

The mill can be run by water-power (free), turbine-wheels the most advantageous. There being only an elevation of 30 feet, high-pressure wheels cannot be used satisfactorily. The ditch is excavated to millsite and in working order. There is a reverberatory furnace that needs some repair; capacity, 2½ tons per charge. The bed and crown is constructed of steatite, of very pure quality, found about a mile from the mine. A most commodious dwelling and boarding house and out-buildings, etc., are to be seen adjacent to the reduction works. A good buggy-road leads into the property.

I now ascend the slope of the hill to mine to No. 1 shaft, hoisting works, blacksmith-shop, etc. This shaft is sunk 171 feet from collar and operated by a horse-whim, but Messrs. W. G. Long & Co., who are opening up and developing under a working bond, contemplate immediately putting in a hurdy-gurdy wheel, with suitable hoisting gear, to enable them to more rapidly and efficiently proceed with their explorations.

The water will be provided by the Tuolumne Water Company at so much per inch, at an elevation above shaft of 130 feet vertical.

On descending the shaft, which is in size 5x12 feet in the clear, and is most thoroughly and securely timbered, following down on the vein the whole distance sunk, we stop at the 100-foot level, which is opened 30 feet to north and south, each way disclosing a good four-foot vein, showing same character of sulphurets as before described. Descending to bottom of shaft to No. 2 level, which is drifted north 170 feet, passing through a fine vein of from four to five feet, the entire distance glistening with the rich arsenical sulphurets—in places showing a heavy percentage. From this point to apex of mountain in vertical hight is 471 feet. This is a very important prospective piece of work, and should be continued north to boundary of the mine, being quite deep enough to prove the value of the property; it will intersect the shoots found in upper works, from which 14,000 tons of rock has been extracted and reduced, yielding an average of $15 per ton. This was worked in 1873-4-5-6. The appliances at that time in the treatment of ore were crude and expensive. What would not pay large profits at that time, will now pay handsomely with greater and more perfect facilities. Furthermore, the sulphurets improve in value and percentage as depth is attained. Coming to the surface, I find the old tunnel through which the mine was stoped out to apex of mountain, on one shoot 200 feet long. This tunnel was entered 320 feet, but not far enough north to intersect the north shoot. A winze was sunk 92 feet that gave exceedingly rich rock, where the $8000 assay came from. This point has not been reached or passed under by No. 2 level, in No. 1 shaft. These old works are all full of water and much caved, but it is being effectually drained day and night by whim at No. 1 shaft.

Passing to apex of mountain, I find the vein cropping out boldly to northern boundary, over 1000 feet; in places 10 to 12 feet of solid quartz, here to a depth of 40 feet free gold was found, that paid in arastra $8 to $48 per ton, but afterward, when the oxidized rock was passed, the gold was no longer free, but same character of sulphurets is here met with that is found to the south. Evidence before me shows clearly the gold run or pay shoot must be fully 1000 feet in length, for the shoots far out in depth at No. 2 level, No. 1 shaft, prove the statement so far opened on.

The same formation with dyke is found over the entire area of the mine, which is 2900 feet by 600 feet, held in two locations. Through the courtesy of the superintendent, Mr. Long, I was escorted over and through the property. He is a thoroughly practical miner of over a quarter of a century of experience in quartz-mining. The works in progress show his sound judgment and excellent capabilities in conducting and developing the mine in his charge. I look forward to see this property in the near future a large producer of the precious metal, as the gentlemen now operating mean to run it to its full capacity. Such sagacity deserves success.

ARGUS.

Calaveras County Mines.

[From our Own Correspondent.]

At Indian Creek district, 3½ miles north of Murphys, Messrs. Cunliffe and Driver are running their five-stamp mill on quartz from their Horseshoe mine, which is opened by a 140-foot tunnel crosscutting the 16-inch vein of $18 rock at a depth of 60 feet. They are also the owners of the Hercules mine—No. 1, which is opened by a shaft 150 feet deep on 18-inch vein of $16 rock; No. 2 is opened by shaft 130 feet deep on 4-foot ledge of $10 rock; Caledonia, a 12-inch vein, of $12 rock; the Sunflower, an eight-foot ledge running $4 in free gold and carrying a large percentage of sulphurets. All of these ledges are in the immediate vicinity of their mill. Country rock is slate. They have their own water for power to mill, during the winter months, and will put in an engine to carry them through the dry season. This interesting group of mines can be connected with the Union Water Co.'s ditches and have all the fall required for power.

Sheep Ranch.

The Sheep Ranch mine of J. B. Haggin & Co. is the leading property of the camp. At this time the shaft is down 1100 feet on the two-foot ledge, with a shoot 600 feet in length to stope from, 20 stamps crushing 2¼ tons to the stamp in 24 hours. There is a force of 63 men. Miners' wages are $2.50 a day.

The Tom Smith mine is opened by a 300-foot tunnel, cutting an 18-inch vein of $17 rock, 150 feet deep. In the Anderson mine an 80-foot shaft shows up a 14 inch vein of $12 rock. These mines are the property of Mr. G. Rodeseni of Mt. Ranch. At El Dorado (Mt. Ranch), Mr. Rodeseni has opened up the Rose Hill mine by a 172-foot shaft, and two tunnels cutting the 18-foot ledge 500 feet deep. There is a 10 stamp mill running by water-power; the quartz mills $5 to the ton. The Gaston Hill property is also owned by Mr. Rodeseni and is developed by a 103-foot shaft on a 20-inch vein of $15 rock.

Railroad Flat.

The quartz mines of this section are looking very promising at this time, though the most of the mines are in the prospecting stage. The Last Chance shaft is now down 40 feet on a two foot vein, milling $20 a ton.

New York mine has a shaft down 140 feet on an 18-inch ledge and the mill is just starting up.

Henry Seemans has a 40 foot shaft with $10 rock in a 20-inch vein.

Beal & Cook have a 75-foot shaft on a two-foot ledge of $20 rock, which is worked by arastra.

Bilse & Ellsworth have a 75-foot shaft on a 10-inch vein of ore, milling $29 50 a ton.

Houst, Beal & Cook have a 30-foot shaft on a 4-foot ledge of $10 rock.

West Point.

About two years ago some San Francisco merchants came into this camp, and becoming excited over the high grade of the ores, bonded everything in sight. Work was begun on a number of the mines, but the steel-like hardness of the granite in which the veins run proved too much for their limited capital, attachments following. With the shutting down of the mines the miners went back to prospecting. Their labor is now bearing fruit in a large number of fine prospects, some of which have been sold. A number of the old mines have passed into other hands able to work them, thus making the coming season promising for the mining interests of the camp. Here, as at Soulbsyville, in Tuolumne, where the same granite and sulphuret ores occur, the veins pinch at from 25 to 200 feet, and then in sinking through 25 to 100 feet of this pinch the veins widen out and are rich. So far all of the mining has been done by hand drill, at an expense of $5 to $15 a foot in drifting. The one thing needed is power drills.

The Blazing Star is owned by Moore, Danford & Page. This property is opened by a 230-foot shaft on a five foot vein of $140 rock, carrying six per cent of sulphurets. Ores are crushed in the company's three-stamp mill.

The Lockwood is perhaps the best-known mine in the camp. At present the company is working to develop larger ore reserves, though at this time they have sufficient ore in sight to run them six months. They have developed the vein by shaft to a depth of 300 feet. Their five-stamp mill is now running and the owners are confident of opening up as large and valuable ore bodies as the Lockwood has shown in the past. Then but 50 per cent of the ore's value was saved, but now close to 100 will be caught.

The Lone Star property will shortly be equipped with a 20-stamp mill, which will soon place it on record.

Mr. Courtiss is developing the Soap Root property, with every prospect of its proving a valuable mine. Miners' wages, here as elsewhere in the county, $2.50 per day. Mr. Carlton's custom arastra is running steadily on rock from the numerous prospects in and about West Point.

Glencoe.

Mr. T. W. Knox is showing what pluck will do and receiving the accompanying luck in return in working the Fidelity. This mine, after sinking 200 feet and meeting with no encouragement, was abandoned some four years ago. Mr. Knox coming into possession, pumped out the water and the second shot knocked the cap off of a shoot on a 3½-foot ledge of $40 rock.

Mokelumne Hill.

At the Ilex the work is all of a prospecting and drilling character, the exceptionally fine plant, unexcelled by any in the State, being idle.

The River mine is the property of Mr. W. R. Petrie of the Ilex. The eight-foot vein is cut 330 feet deep by a tunnel 450 feet long. The walls are diorite. The quartz averages $5 a ton in free gold. The mine is most favorably situated, and by reason of this fact and the fine water privilege enjoyed the quartz is mined and milled for $1 a ton. At present Mr. Petrie is running a 10-stamp mill and driving ahead to develop the mine, not only paying expenses, but netting each month a handsome return from working the mine. Hutchison & Brackett have a four-foot ledge. A shaft 35 feet deep has been sunk, the owners thus far working the selected quartz by hand, mortar and pan, realizing $120 a day for the two men.

Mr. Von Dell is mining on the Calaveras two miles east of Rich Gulch. This ledge is 3½ feet wide and is opened by a shaft 80 feet deep. The quartz is ground in a water-power arastra, yielding $9 a ton.

San Andreas.

The Cordova Union Gold Co. is located 3½ miles southwest of San Andreas. The gentlemen in charge of this property have shown how to bring victory out of defeat. Finding the old ledge of no value, they put down three shafts of 46, 92 and 162 feet on a parallel vein in entirely different country rock (metallic slate). The present vein carries a width of 11 feet with a fine gouge and splendid walls. Mr. Charles Cowland, an English gentleman from the mines of Australia, is in charge during the absence of the superintendent, Mr. Rickard. Mr. Cowland is shoving things with vigor. His feat of breaking ground on the 1st of March and having a 10-stamp steam-mill running with everything inclosed and in place by the first of April, is an Australian way of rushing that California mining men are not accustomed to, and is as much in contrast as Mr. C.'s accounts of the mines that run by the ounce in Australia as compared with California dollars.

The Burgess Mine,

Rathbeg Bros. owners, is but a half-mile distant from the Cordova. It covers 4500 feet on a 50-foot ledge. From the old 102-foot shaft the ore extracted in sinking alone gave $18,000. The present shaft is now down 80 feet and levels run; estimated milling value of rock, $6 a ton. A fine 20-stamp mill has just been put in operation. Frue vanners are on the ground to be added to the plant. The size of the ledge, value of the rock, extent of territory and capacity of the mill must make this a fine proposition.

E. H. SCHAEFFLE.

The Plumas-Eureka.

The editor of the Sierraville *Leader* recently made a visit to the Plumas-Eureka, and has the following to say about the mine: It is a great curiosity for the magnitude of the lodes and their various dips and angles. The ore is found in bodies at every point of the compass, and even horizontally. There are millions of running feet of timber, mostly from 18 to 30 inches in diameter, to be seen almost everywhere throughout the mine. The ore bodies vary from one inch to 20 feet wide, with the peculiar feature before mentioned, viz: that of being found deposited in all directions. The small engines in the various locations throughout the mine are run by compressed air which passes through pipes from the big air-compressing engine that is over 1½ miles away. There is one pump that is run to hoist water from a prospect shaft 140 feet below the lowest tunnel by water instead of steam or air, that has over 700 feet of pressure. The stroke of the water engine is seven feet and makes only seven strokes per minute. In many places the huge timbers are crushed as though they were only a few inches thick. Before the company got compressed air to run the engines, steam was carried 3000 feet in pipes, laid in boxes covered with ashes to keep the steam from condensing. There are over 3000 feet of tramway to conduct the ore down the hill to a 60-stamp mill, which is now being run by water-power. Two hundred men are on the pay-roll at present. There is one tunnel over 1½ miles in length.

PORTLAND papers claim that 5000 hands are employed in the various works of that city. During the past year nearly $3,000,000 has been spent in reviving old industries and establishing new ones, while over $1,000,000 has been expended by established institutions in the enlargement of their facilities.

THE Eel River Lumber Co. bought 920 acres of timber land on Elk river recently for $44,000.

Notes on Leaching Silver Ores.

NUMBER 3.

[Written for the MINING AND SCIENTIFIC PRESS by C. H. AARON.]

Hofmann's trough lixiviation has called forth such animadversion as to necessitate its abandonment or vindication by the inventor, and that gentleman has shown himself equal to the emergency. The fundamental fact on which trough lixiviation is based was known to others, but the appreciation of its full significance and its application in a practical form we owe to Ottokar Hofmann. I have always thought the objections urged against this process of little importance with one exception—it was supposed to require a relatively enormous volume of solution, but this supposition is now shown to be erroneous. On the contrary, a very much smaller quantity of hypo is required in this way than by the ordinary process of leaching in vats.

I have been surprised at the small volume of solution required for some ores, as given in Stetefeldt's book. In one case it seems to be hardly more than enough to saturate the ore; but Hofmann looked deeper and found that the statements were erroneous, as proved by calculation from the given time of leaching and the rate of filtering. In fact it requires from 3 to 20 tons of hypo to leach a ton of ore by filtration, while by the trough system not only is the average quantity greatly reduced, but the rate of the little filtration required is increased from an average of 8½ inches per hour to 12 inches per hour, which falsifies the prediction made by the opponents of the process, that the ore would be so packed and stratified in alternate beds of sand and slime that filtration would be almost impossible. I never attached much weight to this objection, as I felt sure that when the heavy and coarse sand should enter the vat it would so interpenetrate the small quantity of fine stuff already accumulated as to prevent trouble from that cause, and it does so apparently. The greater average rate of filtration in the trough process is to be ascribed to the briefness of the filtering period, for, the longer the filtration is continued the slower it will become in general, unless channels form which are very disadvantageous for the extraction of the silver.

Mr. Ellsworth Daggett regarded trough lixiviation as amounting to nothing more than an automatic method of charging the leaching vats, effecting an insignificant economy. Were this its only merit, it would deserve almost as much consideration as does the similar method of discharging the vats by sluicing the tailings out of them, and it seems strange that those who have taken the pains to point out an alleged economy of a few cents per ton by the use of sodium instead of calcium sulphide should so despise a saving in the cost of charging the vats, though, by the way, Mr. Hofmann proves by statistics that economy in the choice of a sulphide lies on the side of calcium in the particular instance referred to. But the chief merit of trough lixiviation does not consist in charging the vats cheaply, but in the fact that only a very small proportion of the solution has to filter through the ore, by far the greater part of it being rapidly removed by a process analogous to decantation, an advantage which every chemist will appreciate, even though a final (rapid) filtration through a thin bed of sand is necessary in order to obtain a perfectly clear solution.

One of the defects ascribed to this process was the amount of grade required for two sets of leaching vats, and two sets of troughs each with a length of 140 feet; this was little more than caviling, because a mill is always built on a slope if possible, and, in large works at least, it is all the better if the several departments are separated, provided it costs nothing to transfer the ore from the one to the other. But Hofmann has shown that a length of 12 feet of V trough suffices for the washing, and another 12 feet for the lixiviation with hypo, and this fact goes far to invalidate another alleged difficulty, which was that the hypo would oxidize rapidly in consequence of flowing through such a length of trough.

The saving of time by trough leaching of the particular ore in question is enormous, the common process requiring 109½ hours, including the washings, against 15 hours for the same quantity of ore by the trough system; this means a great reduction of plant and housing. Also the quality of the precipitate from the trough process is better than that from the other, which may be due to the shorter exposure of the ore to the dissolving action, causing less lead to be extracted. It has been objected that the effect of the caustic lime in some roasted ores is the same in trough leaching as in filtering, but it may be answered that the remedy is also the same, namely, an addition of acid, sodium disulphate, cupric sulphate or ferrous sulphate to the wash-water, which can be elevated and used again if required, as in such a case any base metal it may hold in solution, as well as free acid, will effect the desired result of neutralizing the lime.

On one point Mr. Hofmann seems to have caught us all napping, himself included, I think. It has been generally, though perhaps thoughtlessly, admitted that in leaching with sodium hypo and precipitating with calcium sulphide, the sodium hypo is gradually replaced by calcium hypo. Mr. Hofmann says he finds this to be an error; the leaching solution remains essentially sodium hypo, and he sustains

the assertion by the analysis of his hypo after more than three months' use. The analysis shows only a trifle more calcium than the quantity which corresponds to the sulphuric anhydride present, and that corresponds exactly with a saturated solution of gypsum; hence Mr. Hofmann says that the process which he first introduced, and which has been generally used in the West, is not the Kiss process. Kiss used calcium hypo for the leaching and the corresponding sulphide for the precipitation; Patera used the sodium salts for both. The process here discussed is, therefore, says Mr. Hofmann, a combination of the two.

The conservation of the sodium hypo is explained by the fact that the roasted ore retains a quantity of sodium sulphate after the base metal leaching, and this, dissolving in the hypo subsequently, precipitates the calcium from the sulphide and from its accompanying calcium hypo, in the form of gypsum. I suggest, as a concurrent circumstance, that the sodium sulphate produced by oxidation of the hypo acts in the same way.

Thus Mr. Hofmann vindicates his "obstinately" adhering to the use of calcium sulphide, against the opinion of Mr. Stetefeldt, by showing on the one hand that Mr. Stetefeldt's objection to calcium hypo on account of its rapid deterioration does not apply, while on the other hand the injurious accumulation of sodium sulphate in the hypo is prevented.

The Government Surveys.

At the last meeting of the State Board of Trade, W. H. Mills spoke of the recent Arid Land and Irrigation Act of Congress, which provides for surveys, etc., leading to the redemption of the arid regions of the Western States and Territories. He spoke of the appropriation of some $3,000,000 for this work and of its great value to all the West, as well as the entire country. The land policy of the country was considered briefly, and the speaker closed by introducing State Engineer Hall.

Mr. Hall has been in Washington lately and has interested himself in this arid land survey project. He gave a history of the bill and commented upon the value to the Territory interested. The plan, in the judgment of the speaker, is the beginning in carrying out the new land policy demanded by the necessities of the country at present. While in Washington he learned that the unappropriated Government land now remaining is surprisingly small. His investigations have shown him that the arid regions of the United States amount to fully 1,300,000 square miles. Of this, fully 15 per cent is mountainous and not irrigable. A large part of the remainder can be irrigated by arrangement of a proper and systematic storage-reservoir system. The committee on the new public-land policy appointed by Congress is regarded as one of the most important appointed since the war. Senator Stewart is chairman, and Senators Allison, Hiscock, Gorman and Plumb are members of the committee. The speaker commented on the fact that the representatives of New Mexico, Nevada and the Western Territories have been urgent in claiming a part of the appropriation and the services of the assigned engineers, but that California had done very little. He urged the need of the State Board or some other body taking the matter up.

Mr. Mills said that he had already interested himself in the work spoken of, and had called the attention of the Geological Survey to the demand of California. On March 24th Mr. Huntington sent dispatches to Major Powell, of the Geological Survey, and to Senator Stewart. These dispatches called attention of the persons addressed to the mountainous region on the west side of the San Joaquin valley, which, it was said, was of little or no value, owing to the lack of water.

The following resolutions, presented by Gen. N. P. Chipman, were adopted:

Resolved, First, inasmuch as the exceptional climate of California, offering not only unusual charms for physical existence, but being of the highest economic value, is attracting universal interest throughout the Union; and inasmuch as there are large areas of rich and productive lands in our State capable, with irrigation, of wonderful results, as Fresno, Riverside and other tropical regions amply testify, we invite the attention of the eminent authorities in charge of the surveys in question to an early inspection of our State.

Resolved, Second, that our delegation in Congress be requested to exert its influence toward securing the most complete examination of our State, and showing its need of some general and comprehensive system looking to the irrigation of large tracts of land incalculably valuable with water, but of little value without.

Resolved, Third, that in our judgment the Government ought to attach to its corps of surveyors and engineers the most competent engineer to be found upon our coast, familiar with its topographical resources and needs, and we ask our Congressional delegation to secure, if possible, the selection of some such person to represent the region west of the Rocky mountains, and if possible, to conduct the survey of that region.

Copies of these resolutions were ordered sent to Major Powell and to the various Congressmen.

Information of the magnitude of the timber interests of Puget Sound has reached the heavy lumber capitalists of Minnesota, and Mr. Winston came out to see what could be done. It is said that a big company, representing about $20,000,000, is about to be organized of Minnesota and Wisconsin capitalists to invest in Puget Sound.

Wild Ginger.

Another of the series of American medicinal plants described by Dr. Vasey, U. S. Botanist, is illustrated on this page. Early mention of others of the series has been made from time to time in our columns. The plant we show herewith is known as wild ginger, and botanically as *Asarum Canadense*. It is a small perennial herbaceous plant growing in rich shady woods on hillsides from Canada to the mountains of North Carolina and westward to Iowa. It is a plant of some commercial importance, for Dr. Vasey says that one firm in North Carolina purchases about 11,000 pounds per year of the roots. The engraving shows, first, the general appearance of the plant, root and leaf, the blossom and the fruit in cross-section. That part which is commonly called the root is botanically called the rhizoma, or a creeping underground stem, usually two or three inches long, and half an inch thick, giving off fibrous roots from the lower side. The extremity of the root stock sends up a pair of kidney-shaped leaves on stalks six to ten inches long. The leaves, when fully developed, are five to six inches broad, and about three inches from the base to the obtuse point. The margins are entire. The leaves and stalks, when young, are somewhat hairy, becoming nearly smooth in age. From between the leaves, close to the ground and terminating the root-stock, there issues a single flower on a drooping peduncle one or two inches long. This flower, when fully developed, is about an inch in length. It has no proper corolla, but a bell-shaped calyx divided above into three oblong, short-pointed spreading lobes, which are of a brownish-purple color inside. The lower part of the calyx is pubescent externally and coherent with the ovary, which above spreads out into six radiating stigmas. There are 12 stamens united to the base of the style, the anthers short. The flower is usually buried among the old leaves which cover the ground where it grows. The fruit is formed of the thickened, fleshy calyx and ovary, divided into six cells, each containing a number of small seeds. The wild ginger belongs to the same botanical family as the *Serpentaria*. The rhizoma or root-stock has an agreeable aromatic taste approaching that of the true ginger, and also somewhat like that of *Serpentaria*. Medicinally it is a warm, aromatic stimulant. It has been employed as a substitute for ginger in common domestic use. The leaves and flowers possess the same taste and quality as the root-stock.

WILD GINGER—Asarum Canadense.

Esmeralda Borax Mines.—No county in the State can boast of more extensive borax works than are those now in operation in Esmeralda, and yet it appears that the laboring men derive but very little benefit therefrom. A stranger walked into town the other day and was overheard to remark that while coming from Candelaria he stopped at one of the principal borax-producing headquarters in the county and asked the gentleman in charge for a job. He was told that if he wanted to work for the same wages then being paid to the Piutes and Chinamen, which he learned was from $1 to $1.50 a day, he could pull off his coat and consider himself engaged. He declined the position and started afoot for Hawthorne. We are painfully aware that Chinamen and Indians are the principal persons employed in and about our borax mines, and why it should be thus is hard to understand. Why would it not be just as well for the owners of these works to give our laboring white men, of whom there are a number at present out of work, a chance to earn an honest dollar, instead of giving the opportunity to a lot of thieving Piutes and hated Mongolians? The mines are fully valuable enough to allow of the payment of decent wages. Several men have made independent fortunes out of these same mines, and it is safe to presume that the present owners are not losing money in their operation. Give the white man a chance.—*Esmeralda News.*

It is understood that the Southern Pacific Company will build new roundhouses at Oakland on an extensive scale. The site has not yet been selected, but General Manager Towne, Treasurer Hopkins, Superintendent Fillmore and others have been surveying the field, and it is thought the work will be begun soon.

The Washington Centenary.

A Proclamation.

By the President of the United States of America:

A hundred years have passed since the Government which our forefathers founded was formally organized. At noon on the 30th day of April, 1789, in the city of New York and in the presence of an assemblage of heroic men whose patriotic devotion had led the colonies to victory and independence, George Washington took the oath of office as chief magistrate of the new-born republic. This impressive act was preceded at 9 o'clock in the morning in all the churches of the city by prayer for God's blessing on the Government and its first President. The centennial of this illustrious event in our history has been declared a general holiday by Act of Congress, to the end that the people of the whole country may join in commemorative exercises appropriate to the day. In order that the joy of the occasion may be associated with deep thankfulness in the minds of the people for all our blessings in the past, and devout supplication to God for their gracious continuance in the future, representatives of religious creeds, both Christian and Hebrew, have memorialized the Government to designate an hour for prayer and thanksgiving on that day.

Now, therefore, I, Benjamin Harrison, President of the United States of America, in response to this pious and reasonable request, do recommend that Tuesday, April 30th, at the hour of 9 o'clock in the morning, the people of the entire country repair to their respective places of divine worship to implore the favor of God that the blessings of liberty, prosperity and peace may abide with us as a people, and that His hand may lead us in paths of righteousness and good deeds.

In witness whereof, I have hereunto set my name and caused the seal of the United States of America to be affixed. Done in the city of Washington this 4th day of April, in the year of our Lord 1889, and of the independence of the United States the 114th.

By the President, BENJAMIN HARRISON.
JAMES G. BLAINE, Secretary of State.

The Governor has issued the following proclamation:

EXECUTIVE DEPARTMENT,
STATE OF CALIFORNIA,
SACRAMENTO, March 30, 1889.

To all whom these presents shall come—GREETING: Whereas, on April 30, 1789, the first President of the United States, George Washington, was inaugurated in the city of New York, this date—as the formal beginning of the present Government of this country—marks a period in the history of the Government of the people, by and for themselves; and as such it is appropriate that the centenary anniversary of this date be observed by the people of this State.

Now, therefore, I, R. W. Waterman, Governor of the State of California, by virtue of the power conferred upon me by the Constitution and laws of this State, do hereby declare Tuesday, April 30, 1889, the centennial of the foundation of the constitutional Government of the United States, and the inauguration of President Washington, a legal holiday; and request that each citizen within the confines of this State refrain from pursuing his usual vocation and so observe the day that he may better appreciate the blessings and glory of American citizenship.

Given under my hand and seal on the day above written. R. W. WATERMAN, Governor.

Attest: W. C. HENDRICKS, Sec'y of State.

Bounty for Artesian Wells in Nevada.

Following is a copy of the substitute Artesian Well bill, which has passed both houses of the Nevada Legislature:

SECTION 1. Section one of said Act is hereby amended to read as follows:

SEC. 1. Every person, firm, company, corporation or association that shall, after the passage of this Act, commence the sinking of artesian wells, shall be entitled for sinking such artesian well, where flowing water is obtained, the following specified sums: For the first 200 feet, $1.25 per foot; for the third 100 feet, $1.50 per foot; for the fourth 100 feet, $2 per foot; for the fifth 100 feet, $2.20 per foot; for the sixth 100 feet, $2.50 per foot; for the seventh 100 feet, $3 per foot; for the eighth 100 feet, $3.50 per foot; for the ninth 100 feet, $4 per foot; for the tenth 100 feet, $4.50 per foot; for all depths exceeding 1000 feet, $5 for each and every foot below the said 1000 feet, and an additional bounty of $1000 for every well sunk to the depth of 1000 feet or more, said well to furnish a flow of 20,000 gallons of water every 24 hours for 30 days successively. Said sums to be paid in the manner provided for in Sections 4 and 5 of this Act, provided that no bounty shall be paid on any well which does not furnish 7000 gallons of water in 24 hours, flowing continuously for 30 days; and provided, further, that no two wells should receive a bounty if located in the same county.

Running a Lathe Without an Engine.—In 1867, when R. Gluyas, now of Hot Creek, Nye Co., Nev., was chief engineer of the Gould & Curry Mining Co., on the Comstock, the engine that ran the machine shop broke down, and he had to fit up a new piston for it. The problem was, how to run the lathe without the engine. The boiler being all right, he got up steam and made a wheel almost exactly like the Pelton wheel. A jet of steam at 60 to 70 pounds pressure was turned on the buckets of this wheel through a fine nozzle. The lathe was run with this and the machine-shop engine repaired. Louis Janin was the superintendent at the time and congratulated Mr. Gluyas on his ingenuity and the success accomplished.

The following railroad companies have been merged into one company, to be known hereafter as the San Francisco and North Pacific Railway Company: San Francisco and San Rafael railroad, San Francisco and North Pacific railroad, Marin and Napa railroad, Sonoma Valley railroad, Cloverdale and Ukiah railroad.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Alameda.

COAL MINE WORK.—Livermore *Herald*, April 12: The Pen Daren incline is now down 330 feet, and at 350, side drifts will be run and the taking out of coal begin at once. The incline is not now on the vein, the latter having changed its dip. It will therefore be necessary to run a drift back to it, some 15 or 20 feet, before beginning the lateral tunnels. The Co. is about to begin a 1200-foot tunnel on the Corral Hollow side, on the Coleman lands, to cut at right angles all the eight coal veins described in the report of Expert Atkinson, which we publish this week. This tunnel will begin near the O'Brien house, and run into the hill at an acute angle with the creek. It will be the great developing tunnel of the district, and open up this property as it never before has been opened. With the completion of this tunnel, not only the exact value of each vein can be determined, but all can be worked at once, and the coal can be taken out from one common tunnel.

Amador.

NORTH STAR.—Amador *Ledger*, April 13: The directors of the North Star Improvement Co. have succeeded in securing an extension of the bond, or rather in obtaining a new bond to the property to the sum of $27,000. The intention is to sink the present shaft from 200 to 300 feet deeper, and run prospect drifts as heretofore.

KENNEDY.—George Thomas has resigned as foreman of the Kennedy. He quit the position last week. J. F. Parks, the superintendent, is also attending to the duties of underground foreman at present. We understand it is the intention of the Co. to commence sinking the main shaft to a greater depth, shortly. The 40-stamp mill is kept going steadily.

MISCELLANEOUS.—The contract for sinking the Alpi shaft 50 feet deeper was completed early this week. The same parties have taken a contract to sink another ten feet, which will give the shaft a total depth of 110 feet. At this depth it is the intention to crosscut the ledge, with the view of ascertaining the grade of ore. At the Amador gold mine the work of putting up the new hoisting machinery is being energetically pushed ahead. Four men who have been working on the Loyal Lead claim for some time, stumbled across one of those rich streaks of quartz which are found in that neighborhood, and during last month extracted $1200, working the rock with a small arastra. Some parties working the Italian quartz claim, adjoining the Loyal Lead, have taken out a large quantity of quartz, which prospects well. They were in Jackson this week making inquiries about a Huntington roller quartz-mill, which they think of erecting on the claim. The last cleanup of the Wildman at Sutter Creek was the best yet made since work was resumed upon the property. The yield, including sulphurets, averaged something over $7 per ton. The ledge is 20 feet wide and it seems to be all of fine quality.

Calaveras.

MOKELUMNE HILL AND VICINITY.—Calaveras *Prospect*, April 12: The Fidelity mine at Glencoe is being reopened by Mr. Ennis. Several men are employed, and present indications are flattering, to say the least. Some very good rock has been taken out of the shaft lately. The Quaker City mine, owned by a San Francisco company, is looking better. A 10-foot ledge was discovered a short time ago. The South Star gravel mine, near Happy Valley, is prospecting well. The machinery from the A and B mine was transferred to the South Star mine last week, and the superintendent, W. H. Curnon, will commence operations in earnest as soon as the mill can be completed. About 20 men are employed in the Ilex mine at Rich Gulch. Supt. R. W. Petree intends to sink at least 400 feet on the vein and may possibly go down 600. The indications are better than they have ever been that the Ilex will yet be opened up and a paying mine found. The Cleveland mine was reopened about a month ago, by W. T. Robinson. This mine is about one mile above the Big Bar bridge on the Mokelumne river. From eight to ten men are employed at present, and a five-stamp mill is kept pounding away on good rock. The shaft is down about 100 feet, and things look flattering. The Allison mine on the Mokelumne river, near the Big Bar bridge, is paying well. A ten-stamp mill is kept running steadily night and day. The vein is from 10 to 15 feet wide, at a depth of 200 feet, and the proprietors, R. W. Petree and Tripp, are well pleased with the present prospects. Last month the dividends amounted to something over $4000. An air compressor and two Burleigh drills are doing good work in the tunnel. W. Hutchingson and John Brackett have discovered a rich streak of quartz near Mokelumne Hill. They are making on an average an ounce per day the last we heard of them, and the indications were favorable for a "good find," if the pay dirt holds out.

THE MCPHERSON MINE.—T. Lloyd and Nick Cusilege have relocated the McPherson mine on Adobe Gulch, near El Dorado. Mr. McPherson expended over $80,000 between the years 1880–82 in working this mine, and finally abandoned it. The present locators have discovered a body of quartz in a tunnel, close to the shaft. It is strange this vein was not prospected by the management when the tunnel was being run. The quartz contains considerable free gold, and it is considered an excellent prospect by parties who have examined the rock.

THE UNION MINE.—The ten-stamp mill at the Union mine was completed last week, and is now running night and day. One of the batteries of five stamps is crushing quartz from the middle shaft and the other battery is running on rock from the old Rathgeb shaft. Work will be resumed on the south shaft in a few days. The machinery is all on the ground for the hoisting works, and it will not take long to get ready to commence sinking on this shaft.

THE BLACK WONDER. — Calaveras *Chronicle*, April 13: We learn that the Black Wonder quartz mine, owned by Messrs. W. W. Cook and Aaron Cook, and located in the Blue mountain district, is showing good rock. The working tunnel is in 300 feet, tapping the lead at a depth of 150 feet. The ledge here shows a width of three feet and by crude process of working yields from $8 to $10 per ton. Ten men are employed and a five-stamp mill is kept running day and night. The prospects are very promising.

BALD HILL.—Angels *Record*, April 9: Mr. W. Boyle, one of the owners of the Bald Hill mine, reports favorable progress. A vein eight feet in width has been struck which shows up very rich. Ten men are employed and we presume that a mill will be built before many months.

GOOD PROSPECT.—Calaveras *Prospect*, April 12: The prospects are favorable for a boom in the Central hill gravel mines this summer. San Francisco parties are expected to look at several mines in that locality soon.

A MINE RELOCATED.—The Oro Fino mine, near Cave City, has been relocated by Henry Charles and Philip Harkins. They intend to open up the old tunnel, which is 212 feet long, and then go down into the winze, which is 60 feet deep. All the old miners who worked in the Oro Fino are confident that a good-paying ledge can be opened up at a very little expense.

GOOD ORE.—Some very rich rock was taken out at the Whittier mine, near Angels, last week.

Inyo.

PALMETTO DISTRICT.—Inyo *Independent*, April 13: There are many prospectors at work in Palmetto district and already several promising discoveries are reported. The district attracted a good deal of attention away back in the '60s, but was soon neglected, and almost abandoned, until quite recently. A few of the early prospectors never lost faith in the district; they staid with it, and these recent discoveries justify their faith. John Kensella is one of the fortunate prospectors in Palmetto district. He has taken out and shipped some rich ore and is reported to have a good claim and to be making money fast.

A REMARKABLE SALT DEPOSIT.—It is doubtful if there is elsewhere in the world a more remarkable deposit of salt than is found near Silver Peak. The salt is almost perfectly pure, the grade by chemical test being 98 per cent. It is shoveled into sacks where found and is ready for use in that state. It is as white as snow and of fine grain. It has been proved to be the finest salt in use for curing meat. When we have a railroad to Los Angeles, meat-packing will be one of the big items of Owens valley business; there will then be use for this fine salt. In Saline valley, across the Inyo mountains, is another vast deposit of salt. Indians gather this salt, pack it over into Owens valley, and exchange it goods.

Nevada.

NORTH STAR.—*Tidings*, April 13: The addition to the North Star hoisting plant will soon be ready for business. In the idiom of the miners, the Coe pump "is lost." A new pump is being put in with all dispatch. Objections have been raised against the traversing of a certain mining claim by the new ditch which is to supply the Omaha with additional water for motive-power. Alf. Tregidgo's bond on the Gold Hill mining property has expired. Mr. J. M. Lakenan has a 60-day bond on it and we understand he has good prospects for reopening the famous old mine. It was stated on the streets to-day that a number of North Star miners will be "let out" to-night, but will be informed that they will be given work at a stipulated price per foot. The miners fear this will prove a step to a reduction in wages, and if such proves the case a determined resistance to the movement will very probably be inaugurated. Three dollars a day is not a cent too much for the work done by the miners, to say nothing of the dangers to which they are exposed.

COE.—*Tidings*, April 12: A valve in the pump at the Coe broke Thursday evening at 4 o'clock, and it is not expected the damage can be repaired and the pump again started before late to-night—perhaps to-morrow morning. During the three days the pump was in operation, the water was lowered 136 feet, and it was expected that the mine would be clear of water in six days more. The East Eureka shaft is down 500 feet and a station is being made at that depth, from which drifts will be run. From indications it is certain that the ledge is close by. Thirty-five men are employed at the North Banner, and drifts are being run from the 100-foot level of the shaft in the lower tunnel. The ledge is of good size and quality. The ten-stamp mill is kept busy night and day.

WATER-POWER FOR THE OMAHA.—Grass Valley *Union*, April 3: Arrangements having been about perfected for a right of way for a ditch through Loutzenheiser's ranch to convey the water from the North Star to the Omaha mine, the work of construction will be commenced as soon as practicable. By this arrangement Mr. Loutzenheiser will secure a fixed amount of water for irrigating purposes, and the Omaha 200 inches of water additional to what it has now, and under considerably more pressure with which to drive its hoisting and pumping machinery. The water of the North Star has heretofore been running into Squirrel creek, but by the proposed diversion the waste water will go into Wolf creek, and will be that much in addition to what has been previously going down the creek, which has been utilized to a large extent for irrigation.

Placer.

GRAY EAGLE PUMPS.—Cor. Placer *Herald*, April 6: The Co. has put in some good machinery and everything is going all right. There is a big link-motion engine, 75-horse power, which runs the plunger pump. The plunger was set down 130 feet at first, and after pumping down a way steam pumps were put below to pump to a tank at the plunger. After getting down about 100 feet the steam pumps threw to the top and the plunger was lowered to the pump and stationed permanently. The steam pumps were then used to throw the water to this point till the bottom was reached, then they were hauled out and a jack-head bucket-pump put on the bottom. These pump rods were hung to the rods of the plunger so both pumps run on the same stroke. There are about 20 inches of water, which is handled on seven strokes a minute. All the steam pipes have been hauled out, new ladders put in from the bottom, the shaft boarded, rubbish cleaned out, and will begin sinking Saturday or before. They expect to sink about 20 feet, depending on the rock, and then commence drifting. Everything is in good shape and the indications are that this will be a good mine.

Shasta.

FLAT CREEK.—Redding *Free Press*, April 13: Andy Fife is talking of operating on Flat creek this summer. Flat creek is undoubtedly a rich mining camp, although the crude method of working the ore in the past, and the consequent loss of the gold, has given the mines of that section a black eye. The gold is very fine and floats off.

Sierra.

THE SUNFLOWER. — Sierra *Tribune*, April 12: The Sunflower quartz mine is situated at the town of Pike in this county. A. S. Winchester is superintendent and president of the company, which was organized by Oakland people, although a large part of the stock is held in the East. The Nevada *Transcript* says a tunnel has been run in from Texas creek a distance of 495 feet and is supposed to now be within 30 feet of the ledge. It is expected that banks of 190 feet will be obtained. A shaft was put down 75 feet from the brow of the hill, and in the bottom of the shaft is a ledge four feet wide and 11 inches thick, showing some gold.

ASSIGNED WORK.—*Mountain Messenger*, April 13: Some of the men, liberated by the draft, on the Buttes' force, at Sierra City, have been again assigned work by the company.

EXTENSION.—Twenty-eight feet were made by the Bald Mt. Ex. Co., last week, in their new main tunnel, near half a mile in the ridge, and the indications are that the tunnel is through the rim and under the channel, to which an upraise will soon be made.

San Bernardino.

BLACK HAWK.—San Bernardino *Courier*, April 11: Mr. J. B. Cook, of the Black Hawk mines, is in the city, and we glean the following mining news from him: Messrs. Hanchett and Freeman have leased the old Gold Mountain property (Baldwin) in Bear Valley, and are about giving the ore a thorough test, using concentrators to save the sulphurets. It is quite probable that the use of concentrators will enhance the value of the large ore body, so as to make it a feasible undertaking. A new superintendent will arrive in a few days from England to take charge of the Valley Gold property in Holcomb, Mr. Del Mar having resigned the management. It is said to be the intention of the company to push work during the coming summer. The Old Morongo patented mine is putting on a few men with a view to large developments. Judge Nichols has J. M. Miller and Mr. Jones of Los Angeles associated with him. This mine has lain idle for years with a considerable body of ore in sight. There are three shafts, one of 100 feet, one of 60 feet, and one of 30 feet in depth, showing fine ore in the bottom. They intend putting up reduction works in the near future. The Black Hawk mines are now open for the largest kind of reduction works. One of these mines is said to have been sold to an English syndicate, and the erection of a 40-stamp mill will be commenced at once at the mines. Adams, Driscoll & Co. have shipped and received their returns from Selby & Co., San Francisco, of a carload of gold ore from their mine, about 12 miles northeast of Victor, giving a result of $60 a ton. They have a shaft down 100 feet, with drifts 30 feet each way on the vein. It is the making of a fine mine.

Trinity.

EAST FORK.—Trinity *Journal*, April 13: Work is being steadily pushed on the Golden Chest in the way of development and taking out ore. The ledge in the main tunnel is about 18 or 20 inches wide, and in the breast four feet. There is plenty of good-looking ore in sight. The mill is running, crushing five tons a day. Tinsley's train is now packing 100 tons of ore from the Red, White and Blue mine to the Golden Chest mill, where it will be crushed. The Davis brothers on Yellow Jacket have a good prospect; they are running a tunnel on the ledge, which is about 18 inches thick, and is good-looking rock. In the Alaska, also on Yellow Jacket, stringers have been struck in the tunnel and indications point to finding the main ledge in a few days. The tunnel is now in over 100 feet. The Enterprise has plenty of good rock in sight, and work is progressing satisfactorily. The arastra is grinding away on $100 rock, and the mine turns out dividends as regularly as clockwork. The company will put up a stamp-mill as soon as the wagon-road is completed. Day & Greenwell are taking out ore from the Ozark; they are working on as good ore as ever and have about 30 tons on the dump, which they will crush shortly. Past crushings from the Ozark have yielded $100 to the ton. A drift has been run in on the Fountain Head, Barney gulch, and the ledge runs from two to four feet and prospects well. The rock is good milling ore, and the mine has a firm future. The Simmons brothers are running a new tunnel on the Webfoot, east of the old tunnel, to tap the ledge lower down. The Poor Man on East Fork has most excellent prospects. This mine joins the Enterprise and North Star mines and carries a large body of ore, the vein matter in places being 15 feet wide, and prospects for its entire width. Even the dirt and debris from the mine prospects. In cutting the new wagon-road, three veins of quartz were exposed on the Fritz mine, owned by Meckel & Day. Day & Otto Hippler have made a new strike on Rich gulch. The ledge runs from 20 to 30 inches in width, carries free gold and galena sulphurets, and the ore is estimated to go $20 a ton. The ledge is well defined, with walls of granite and porphyry. This was the first prospect found by Day in the camp, but he did not work at it until lately. On the whole, everything points to a busy and prosperous year in East Fork. The ledges increase in value as work progresses; several new mills will be erected on the completion of the road; a sawmill will be put up, and a well-stocked store be put in operation.

CANYON CREEK.—Cor. Trinity *Journal*, April 9: As the recent discovery of gold-bearing quartz on Canyon creek is causing quite a little ripple of excitement among the people of this locality, perhaps it would be about right to give outsiders a chance to know in what direction their future fortunes lie ready, waiting to be uncovered. Canyon creek, a branch of the Trinity, some 30 miles in length, rises in the Salmon range of mountains, flows in a southwesterly course, and empties into the Trinity river nine miles west of Weaverville. It has been one of the richest streams ever worked in the county; the high benches and low bars have long since been mined off, until nothing much else is left than unsightly mounds of boulders and bare rock. If the marvelous tales told by the oldest inhabitant are to be believed, men have been made rich by a single barrow-load of pay dirt. East Fork and Canyon creek both have their source in the same range of mountains, run parallel with each other, a dividing ridge between the two, in some places very low. While gold ore was found many years ago on East Fork, and for the last two or three considerable prospecting has been done on Canyon creek, nothing was found until six weeks ago, and since that time a number of veins have been discovered carrying free gold and galena sulphurets with a large per cent of silver. The lodes so far found are wider than those of East Fork, most of them being from 6 to 8 feet in width and are strong veins likely to hold out as they are developed. Fisher gulch, one-quarter of a mile above Canyon City, is where the first locations are met with; the next are on what is called Big East Fork, three miles above town; then comes Little East Fork, one mile further on. All of the prospects are found high on the mountains, showing conclusively that slides were the cause of depositing the gold in the stream below. Toward the headwaters of the creek a large body of magnetic iron is met with, causing considerable trouble to surveying parties who have, at different times, crossed those mountains. Some rich specimens of cinnabar float have been picked up on what is called Mogul Hill, one mile this side of town. No doubt an experienced prospector of that mineral could succeed in finding the vein whence came the float.

A NEW MILL.—Trinity *Journal*, April 13: Mr. Frank Peterson of San Francisco arrived Wednesday, and left for East Fork Friday. Mr. Peterson is interested with Capt. Trueworthy in the Fountain Head mine in that district, and visited the mine last week. He was so well satisfied with the prospect that he has purchased a Huntington mill with a Challenge ore-feeder and three concentrators. The mill has a guaranteed capacity of from 25 to 35 tons a day, and will be shipped from the city Saturday, and will be taken in as soon as the wagon-road is completed.

NORTH STAR.—Capt. Trueworthy of East Fork was in town this week and is quite jubilant over the North Star mine in which he is interested with Mr. Henry Junkans. There is a fine body of ore in sight and some very rich rock has been discovered.

Tuolumne.

NEW MILL.—Tuolumne *Independent*, April 13: A new five-stamp quartz-mill, with engine and boiler, has been purchased in San Francisco for Lyman Tibbit's Eagle creek mine. It is on the road and will be on the ground in a few days.

GOLDEN GATE.—At the Golden Gate mine grading has commenced for the new hoisting works, which will be of a capacity for sinking 1000 feet. They will be erected at the mouth of the old tunnel, at which point the present shaft is 170 feet deep, and a level extends 215 feet under the old works to a point beneath the old shaft, which extends from the ore shoot at the top of the hill. It is proposed to connect with this shaft later. As soon as the hoisting works are finished the new shaft will be sunk 100 feet and another level of 270 feet run. This will be at a depth from the surface croppings of more than 400 feet. It is known that the present shoot has a length of at least 800 feet, and the vein runs from four to six feet in width. There are two parallel veins—one on each side—within 60 feet, with a width of two feet, and several small cross veins. Some of the rock, sent below and tested by working process, yielded $169 to the ton, and the poorest went over $40. The property is owned by the Alaska Fur Co. of San Francisco. They intend to thoroughly develop the mine before erecting a new mill. Superintendent W. G. Long is confident o large results.

REOPENED.—Messrs. Richards & Knapp of Columbia have recently opened up the old Richards placer gravel mine, above Springfield. Some very rich diggings were in that neighborhood in early days.

TIOGA DISTRICT.—*Union Democrat*, April 13: Now that Senator Hearst has taken hold of some mining property in the district, it is probable that something will soon be done toward opening the mines. We have received information from a reliable source that there is already considerable machinery destined for Tioga ready for shipment in San Francisco, and that contracts will soon be let for hauling the same to the mines. This is an indication that Senator Hearst intends to commence operations at once. If this is the fact, Tioga will experience a lively mining boom the coming summer.

Yuba.

SMARTSVILLE. — Marysville *Appeal*, April 11: Daylight appears in the incline in the Blue Point mine, and as soon as a bulkhead is put in work will be commenced upon the hoisting works. The manner in which the company is pushing the work and making extensive and expensive improvements bespeaks the confidence they have in being amply repaid for this enormous outlay by the returns from the mine. The other companies who propose commencing operations soon are not idle. Preliminaries are nearly completed, after which the welcome ring of pick and drill, saw and hammer will be heard.

NEVADA.

Washoe District.

HALE AND NORCROSS. —*Enterprise*, April 13: On the 400-level north drift from No. 1 west crosscut now advanced 45 feet and continues in fine ore; in the south drift from joint west crosscut are stoping ore of good quality. In the south upraise are putting in ore chutes and preparing to take ore from this part of the mine. On the 500-level the northwest crosscut is now advanced 60 feet. The north and south upraises continue in excellent ore from the top of the south upraise. Have made an air connection with the winze south from the north drift, 400 level, which greatly improves the ventilation of the 500 ore stopes. On the 600 level are extracting ore of fair grade from the several stopes. On the 700 level the south drift is now advanced 35 feet and continues in good ore; have commenced putting in square sets in this new find. From present appearances it will produce a great deal of ore. During the week hoisted 1068 tons of ore and shipped to the Nevada mill 930 tons, and milled 1080 tons. Average battery assay, $30 per ton. Have shipped during the week $21,271.26 in bullion.

SAVAGE.—On the 500 level the upraise from No. 3 west crosscut was extended 18 feet and the face is

in quartz showing fair assays. From the south drift on this level are extracting ore from the old stopes, also from No. 3 east crosscut, 600 level. During the week hoisted 525 tons of ore, and shipped to Rock Point mill 508 tons and have milled 512 tons. Average battery assays $19 per ton. Shipped during the week $9211.83 in bullion, the total yield for the month being $28,588.02.

CONFIDENCE.—The joint Challenge-Confidence north drift on the 300 level now in 50 feet, 31 feet having been added during the week. Face in vein material. The joint Challenge-Confidence raise from 300 level is up 14 feet, having been commenced during the week. The top of this raise shows ore of fair quality. Shipped to the Brunswick mill during the week 34 tons of ore, the average battery sample of which shows a value of $25 60 per ton.

ALPHA AND EXCHEQUER.—On the 382 level the northwest crosscut is in 70 feet. Face in clay and porphyry. The northeast crosscut is in 68 feet. Face showing streaks of quartz, clay and a little water. On the 500 level the north lateral drift is in 427 feet. Face in quartz and clay, and the ground is very heavy, with a little water. The northwest crosscut is in 271 feet. The face is in hard blue porphyry.

SEG. BELCHER.—The west crosscut on the 1100 level is out 189 feet, having been advanced 36 feet during the week, or at the rate of over five feet per day. Have cut two more streaks of quartz from 12 to 18 inches wide, which yielded very fair assays. The face is in soft porphyry of the same character as they have been in for the past 50 feet.

BELCHER. — The 200 east crosscut was advanced 35 feet during the week; total length, 175 feet. No change in the material encountered. West crosscut advanced 20 feet; total length, 115 feet. Face in vein material. The 1100 east crosscut is out 66 feet. Have stopped it and started a west crosscut opposite it.

POTOSI.—West raise, 930 level, 400 feet south of the shaft, is up 42 feet; face in porphyry and low-grade quartz. South drift, 850 level, is out 143 feet; face in hard ground. South drift 750 level, is out 379 feet; face in porphyry. West drift, 650 level, is out 42 feet; face in low-grade quartz.

CROWN POINT.—The various stopes looking and yielding about the same as last week. Are engaged in cleaning out the 400 west drift to get into Nos. 1 and 2 crosscuts there. Shipped to the Mexican mill 763 tons of ore during the week, the average battery assay of which was $19.31 per ton.

ALTA.—Are still raising toward the 400 level, preparatory to crosscutting toward the Keystone vein and prospecting it. The usual quantity of ore is being extracted and milled from the 800, 825 and 925 levels.

CHOLLAR.—North drift, 850 level, is out 80 feet; face in very hard ground. North drift, 730 level, is out 131 feet; face in clay and porphyry. North drift, 550 level, is out 881 feet; face in low-grade quartz.

OVERMAN.—Extracted 240 tons and 1200 pounds of ore, and shipped to the Vivian mill 322 tons and 1760 pounds of ore. Shipped one bar of bullion valued at $7658.

CHALLENGE CON.—During the week shipped to the Brunswick mill 83 tons of ore, the average battery assay of which was $25.64 per ton.

SCORPION.—West crosscut on the 350 level advanced 15 feet the past week; total, 455. Face in porphyry.

BALTIMORE.—Work of exploration is progressing favorably on the 225 and 338 levels in drifts westward.

JUSTICE.—The mill is running steadily and the mine is producing the usual quantity of ore.

ANDES.—Still drifting on the 175 level to connect with the West Con. Cal. & Va.

YELLOW JACKET.—Prospecting is going on vigorously in the upper levels.

NEW YORK AND SILVER HILL. — Are still repairing shafts.

Columbus District.

CANDELARIA'S BOOM.—Esmeralda *News*, April 13: It now begins to look as if Candelaria, that old stand-by, was about to throw off the spell of gloom that has seemingly surrounded it the past few years, and resume its station in the ranks of the lively camps of the State. Col. Sutherland, in company with English capitalists, paid Candelaria a visit last week, and after spending a few days in examining the mines returned to San Francisco last Monday. From the meager reports received, it appears that the visit of these gentlemen means much for the benefit of the camp. It is understood that Mr. Sutherland, on behalf of English capitalists, has purchased considerable mining property situated in and about Candelaria, and he intends to begin operations on them immediately. Notwithstanding the fact that Candelaria, for the past year or so, has been considered a played-out camp, its bullion shipments have been as regular as the breaking of dawn. Certainly the shipments were not as large or as numerous as in days past, but the discount on silver is the sole cause for this. Our sister town does not depend solely upon one mine for support. There are the Mt. Diablo, Georgene, Lucky Hill, Chief of the Hill, Potosi and others too numerous to mention, which, with proper management, could be made sources of revenue. Should Col. Sutherland's plans materialize in a sale, which we have every reason to believe at this writing will be the case, the Georgene mill will be run to its fullest capacity, and it would not surprise us in the least to know that the big mills at Belleville had been overhauled and were busily crushing the ore hauled to them by the C. & C. from Candelaria. The Holmes is a big mine and to work it will necessitate the employment of at least 150 men, to say nothing of the fuel, water and the like necessaries.

Lodi District.

ILLINOIS.—Belmont *Courier*, April 13: A. J. Wilkerson informs us that Alfred Welsh is extracting rich rock from the Illinois mine. He shipped 52 tons of silver and gold ore to Reno during last month. Ore from the new strike goes as high as $500 to the ton. Mr. Wilkerson also informs us that the Downey Bros. are prospecting in Mammoth mining district near Downeyville.

ARIZONA.

VEKOL.—Florence *Enterprise*, April 13: Mr. A. H. Elliott has secured a bond on the Combination shaft and the three claims it is intended to develop at the Vekol camp, and will continue sinking for the ore body which it is believed will be encountered at a depth of 210 feet. The shaft is now down 167 feet, leaving but 43 feet of work to reach the ore body, which dips upon the adjoining claims toward it. The mill of the Golden West Mining Co. is being erected at the mine, below the Vekol, and will be in readiness to begin operations as soon as water is reached in the well. The new tunnel to tap the ledge at considerable depth is being pushed forward as rapidly as possible and when the ore body is reached it is confidently believed that a pleasant surprise will await the stockholders.

MOHAVE COUNTY.—*Miner*, April 6: Two carloads of ore from the Copper World were shipped from Yucca to Prescott this week. The Keystone mine, it is said, will soon begin active work. Twenty-five miners have been engaged to work as soon as everything is ready. If this be true it will be glad tidings to the citizens of Mineral Park. From Stockton Hill comes the following item: A strike was made in the Silver King, Stockton Hill, this week, of from 9 to 18 inches of ore that will go 150 ounces. N. C. Amer, the owner, is sinking a shaft and is working three shifts. In December last Mr. Fred E. Murray obtained a working bond on the Copper World, 12 miles south of Yucca, and the work of prospecting the property was begun under the supervision of Mr. H. C. Church, and a great deal of work has been done in running levels, sinking winzes, and like work. All the work done has been in ore, and on the upper level and winze large bodies of ore have been uncovered. All the work done has been with the view of finding the extent and richness of the ore. The ores are carbonate and sulphide, and are 35 per cent copper. The ore taken out in the workings is now being shipped to Copper Basin near Prescott, to be used in matting other ores at the furnace there. The Copper World is now the property of Messrs. Phelps, Dodge & Co. of New York City, who own large copper interests in this Territory.

MAYFLOWER DISTRICT.—Clifton *Clarion*, April 5: Mayflower district is situated on the eastern boundary line of this county, about 20 miles south of here, and although no apparent attention has been given to it, nevertheless there are leads of great value there. Ike Hahn and Tom Moss are the owners of one of the most valuable of these, upon which they have three locations, viz.: The Gazelle, Mount Vernon and Grand View. The ledge crops out boldly for the entire length of the claims (4500 feet) and is on an average eight feet in width. The ore is a carbonate, red oxide and copper glance carrying silver from ten ounces to over 100 ounces per ton. The formation is felsite and porphyry. There is plenty of wood and water adjacent and a splendid wagon-road has been built from the Gila river, eight miles distant on the line of the A. & N. M. railway, to the mines. A mill and smelter could be run by water-power and supplies could be dropped on the line of the railroad at the plant. Some exceedingly rich gold specimens have been shown about Morenci and Clifton of late from Campbell and Muir's gold strike in Gold Gulch, and reports are to the effect that the property is increasing in value as depth is attained.

BRADSHAW MOUNTAIN.—Cor. *Journal-Miner*, March 27: Since the last storm snow is fast disappearing, and work is being energetically prosecuted on a number of mines in this, Tiger district. Mr. Britingham, with a force of men, is taking out ore from the Eclipse. This mine has been known to be rich ever since its discovery, which was in the spring of '71, but owing to the enormous expense of transportation, chloriding was then out of the question. The Eclipse carries high grade ore, assays of which run up in the thousands. The character of the ore is horn silver and black sulphurets. Another valuable property is the Cougar and Eclipse, owned by E. J. Junior. These are the discovery claims of both Cougar and Eclipse. Mr. Junior has done a vast amount of work and developed large bodies of high grade ore. Owing to the great amount of rain and snow last fall and winter, water has retarded work somewhat, but Mr. Junior is now running a crosscut tunnel, which, when completed, will drain the mine to quite a depth and open up a large amount of rich ground for stoping.

PLACERS.—Prescott *Courier*, April 4: Placer miners of Lynx creek, near Prescott, are taking out about $300 in gold each day. Those of the Hassayampa, Big Bug, Turkey creek and the gulches are also doing well. Castle creek and Weaver contribute largely to the gold product. The railroad yard contains a great deal of coke for the Copper Basin Co., which will soon make its first shipment of bullion. It is the company's intention to run a large smelting plant in the Basin on ores from Slate creek and other adjacent camps. The Dixie Co. have everything in readiness for their mill. All miners say the Congress "takes the cake." It is opened nearly 700 feet, and the rich ore is abundant. Owners of idle mines should give leasers a chance to do development work. A big cleanup of gold will soon be made at the Howard mill, ten miles south of Prescott.

DAKOTA.

REDUCTION WORKS.—Mr. Hickok, cashier Deadwood bank, returned Sunday from an Eastern trip made in the interests of rebuilding the works, and on being interviewed stated that he had $30,000 pledged by responsible men, with a proviso that the remainder shall be raised here, and that when the works are rebuilt they shall be free from debt. Mr. Hickok estimates the balance required over the $30,000 at from $12,000 to $15,000. The directors have not yet had a meeting, and hence no plans adopted for raising the amount. There will be no doubt some little delay in rebuilding, awaiting the results of tests being made by Mr. Clark on a new roaster. The works will, however, be rebuilt, and profiting by experience gained in the erection of the works burned, the new ones will be nearer perfection. Those who have pinned their faith to and invested their money in Ruby mines, and erection of reduction works, will yet reap a rich reward. As an illustration of the amount of good ore in the district, there is $100,000 worth of ore on the mill dump (not at or in the mine), and this amount was taken principally from one mine—the Golden Reward— and yet that one mine has hardly been opened. The profits on this ore will alone pay for the works, but as every one knows, money in Deadwood is scarce, and to raise even $15,000 is no small undertaking, yet this is our only salvation, and we must raise it.

NEW LIFE IN AN OLD CAMP.—Deadwood *Pioneer*, April 13: Among the promising properties in the Garden City district is that owned by Dan Flickenger, being situated at the head of Blacktail and comprising four full claims, opened at different places and showing considerable high-grade ore. Further down the hill, toward Garden City, is the well-known property of Keith, Forrester and Clarke. Their property lies on the east side of Spearfish road, and embraces in all five claims. The Eva, on account of having been more carefully prospected and opened, is the most promising of the group. The ore throughout the entire group is said to average $25 in gold to the ton. Perhaps the best developed property in the camp is the Garden City, owned by the Garden City M. Co. The main tunnel is 65 feet long, with numerous crosscuts, exposing the ore vein the entire distance. At the mouth of Elk Horn gulch William Phillips has five claims, from which he has taken some of the richest ore yet discovered in the camp. The ore bodies on this property are extensive. Specimens showing both native gold and silver are frequently broken from the ledge. These discoveries have created no little excitement among the prospectors in the vicinity of Garden City, and many new locations are daily made.

LOWER CALIFORNIA.

THE PLACERS AND QUARTZ.—San Diego *Sun*, April 13: W. R. McFarland returned yesterday after having spent 33 days prospecting in the Santa Clara district. "I think the estimate that 2000 miners and prospectors are now in the district is about correct, and of that number I should say that 1000 are Americans. The camp in American gulch has been abandoned, and the camps in Mexican gulch and at Alamo only remain. A good many miners are employed on the placers. The water in Mexican gulch has partially given out near the middle, but near the source and mouth of the gulch the supply is plentiful. This gulch has been abandoned by all except those who hold good claims. The prospectors and hangers-on left it some time ago. Of those who remain nearly every one is making good wages. One party of three persons with whom I was personally acquainted, stated to me a few days before I left that they were making $12 apiece per day, and they are men perfectly reliable. Jno. Whitcher of San Diego has a claim on which he worked a long time and made nothing. At last he found gold and he told me that he had struck it rich. He was jubilant over his prospects and had taken out $44 in two days. Captain Friend worked a poor claim for three weeks, at the end of which time he found some gold and took out $20 in one day. It did not last, however, and Friend moved to the Alamo district, where he is now prospecting. At Alamo the miners are working both the mesa and creek bed. On the mesa for an area of two or three miles, gold is found in the first six or eight inches of earth. The gold dust is found in a kind of decomposed granite, which is taken down to the creek and washed. This is regarded by all old miners as a very peculiar find. It is such a singular thing that miners are unable to account for the presence of the gold on the mesa in the decomposed granite. The Alamo flat or gulch varies from a few yards to 200 yards in width, and the gold is found on the surface of bedrock, which is from 10 to 15 feet below the surface. One party has run a ditch in Alamo gulch for nearly 200 yards at a depth of from 10 to 15 feet. There is a great deal of gold in the surface rock about the ledges. One company are making it their entire business to gather up all the surface or float rock they can find. I saw two prospect holes that had been sunk 20 feet each, and at the bottom the quartz was just as rich in gold as at the surface and of the same character all the way down. Those sinking shafts will go on down 100 feet, and all the old miners say that if the quartz holds out at that depth, the fact will be established that the richest find in many years has been made. It is the opinion of the miners that the quartz will hold out and that the indications are excellent. I saw several prospect holes where quartz had been pinched out at a depth of four or five feet." Mr. McFarland said that there were a few coming into the mines and a number coming out.

MONTANA.

ANACONDA —*Review*, April 11: The exceptionally fine weather the past month has caused all who were interested in prospects and claims adjacent to Anaconda to start up spring work. Work around Silver Lake has started up fully six weeks in advance of last season. Johnson Brothers, who have a very promising silver claim called the Silver Wedge, located about a mile east of the lake, are taking out some good ore for shipment. The owners of the Silver Reef are sinking a new shaft from which they can more advantageously work the mine. Howard and Rice are working on a claim, just this side of the lake, taking out ore for shipment. At Georgetown the people are confident of a boom this season. An important strike was made last week in the Southern Cross, which is of a permanent character. The Red Lion folks will have their mill ready for work, they think, in about twenty days. They have one of the best looking properties in the district. The Pyrenees is still working along as usual, very little being said about it, though it is really a better property than ever. Supt. Moore does not care to say just what their plans are for the season. The Cable mill is not running just at present, but will start up again soon. There is a rumor that they have now struck another very rich pocket.

OREGON.

PINE CREEK.—Cor. *Union Scout*, April 11: The State mine is one mile north of town, and is the property of Bolles, Senor & Brown. The ledge is seven feet wide with three feet of solid ore. The ore is dark, like black silver sulphurets, containing, however, but little silver, but, using a common expression, is "lousy" with free gold. The wall rock of slate also carries gold in paying quantities. The average of all the ledge matter assays—or rather mills—$30 per ton. This ledge runs, in direction, a little east of north, directly over the mountain, and work can be commenced on the ledge, increasing in depth six inches from the surface to each foot of tunnel. It is most favorably located, as a good wagon-road runs to the mouth of the tunnel. Water-power in a small stream lies within 15 feet of the tunnel, with timber on the ground sufficient for an almost endless exploration of the mine. This location is about three-fourths of a mile from the O. G. M. Co.'s mill which drops 20 stamps. Its accessibility with its surroundings of wood and water-power make it really a bonanza for some one with capital. At the depth of 15 feet from the surface a "lime horse" was encountered, which is gradually diminishing in size, but has all the way carried gold on an average of $17 per ton, so it may be safely said that all inside the walls carries gold in paying quantities. The same description and remarks will apply equally well to other mines in its immediate vicinity, among which are the Comet, Way Up and George. The Comet is three feet between walls of solid quartz carrying gold, with sulphurets carrying $2 or $3 in silver. Twenty sacks produced $12 of free gold, besides the metal left in the tailings, which assays $20 per ton. It is generally shown that about one-half or one-third is saved on the plates. The ore from these mines requires roasting, but the working without roasting loses none of the gold. Parties are now putting in chlorination works similar to those now in operation at Deer creek, Nevada City, California.

BAD SEASON.—Jacksonville *Times*, April 11: The mining season is a comparative failure. Thomas Cook of Foots creek district has struck some very rich quartz, and recorded his notices last Friday. From E. Manville we learn that Messrs. Harvey & Hart have struck an old channel on Jackass creek which prospects as high as 25 cents to the pan. G. W. Bailey and son of Applegate precinct are prospecting a very promising quartz ledge, the ore from which is full of free gold and assays high. They are running two tunnels.

UTAH.

REVIEW.—Salt Lake *Tribune*, April 13: The week has been rather a slim one as regards the production of bullion. Receipts of ore have, however, been fair. For the week ending April 10, inclusive, the receipts of metals in this city aggregated in value the sum of $101,546.55, of which $23,040 was in bullion and $78,546.55 was in ore. For the previous week the receipts were $168,852 in the aggregate, of which $111,967 was in bullion and $56,885 was in ore. The Ontario product for the week was $36,702.10 from ore sales; no bullion. The output of the Daly for the week was $17,083.80 from ore sales; no bullion. A curiosity in the mining world has been the fluctuations of the Horn Silver stock, which has for a month now been quite active in New York; 630 shares of it selling last week at prices ranging from $1.35 to $1 50. No ore strikes have been made in this mine, but the change of management gave confidence that there would be no waste or extravagance, and this confidence has been justified. Limited ore production and economical expenditures have left a fair surplus in the treasury. Base bullion receipts in this city for the week were to the value of $13,700. The Hanauer smelter produced during the week, bullion valued at $9340. Ore receipts in this city for the week were to the value of $57,856.55 by Wells, Fargo & Co., and $20,650 by McCornick & Co.

For New Subscribers—Something New and Rare.

PACIFIC COAST RELIEF CHART.

PHOTO-FACSIMILE.

With subscription paid one year in advance for this paper, and 10 cents to pay postage and mailing tube, we will send a fine Photoplate Relief Chart of the Pacific Coast, embracing California, Nevada, Oregon, Washington Territory, and part of Montana, Idaho and Utah, Photographed from a topographical relief model in plaster (5 feet 3 inches by 5 feet 6 inches in size), made recently by Isaac Winston and Prof. Geo. Davidson (the latter Chief of the U. S. Coast Survey on this Coast for the past 20 years).

While it does not take the place of an ordinary map, it illustrates, comparatively, the elevations and depressions of the principal mountains, valleys, rivers, lakes, ocean and bay-shores of the Pacific States and Territories, and makes a permanently useful, handsome and desirable picture for either library, office or home.

The charts are 19x24 inches, well suited for framing, if desired. It is as handsome, and even more durable, than an ordinary photograph. Seldom is so choice an article offered as a newspaper premium. Sent to old subscribers on the same terms on paying one year in advance of current date. Subscribe and secure this permanently valuable chart.

Address Publishers of this paper, No. 220 Market St., S. F.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this Coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific Coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this Coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That this is understood and appreciated, is evidenced by the number of patents issued through their SCIENTIFIC PRESS Patent Agency (S. F.) from week to week and year to year.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

A. F. JEWETT—Tulare Co.
F. B. LOGAN—Southern California.
H. G. PARSONS—Southern California.
GEO WILSON—Sacramento Co.
J. C. HOAG—San Francisco.
CHAS. F. BLACKBURN—Idaho.
FRANK S. CHAPIN—Colusa Co.
MRS. E. J. STEPHENS—Sierra Co.
R. G. HUSTON—Montana.
E. H. SCHAEFFLE—Calaveras and Tuolumne Cos.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, *or beyond the time he intends to pay for it*, let him not fail to write us *direct* to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or of some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

MECHANICAL PROGRESS.

How to Harden Thin Plates

The *American Machinist*, in reply to a correspondent who wishes to harden steel plates one-eighteenth of an inch thick, says the following process will meet with complete success:

Provide two pieces of iron about 6″x6″x1″, with one surface on each block planed, spread a liberal supply of good sperm oil on each planed surface, place the blocks near by in level position to insure an even thickness of oil, and keep the blocks cool. Immerse the steel plates in molten lead as far as they are required to be hardened; when a red heat is obtained, drop the piece quickly upon the oiled surface of one of the iron blocks, and simultaneously lay the other iron block upon the work; when cool they will be found true. This system has been used for years for hardening thin steel tools with universal success.

A correspondent of the same journal also suggests the following to accomplish the same end:

Sheet-steel of the dimensions stated can be successfully hardened between two cast-iron blocks placed in a screw press or any kind of hand press; holes should be drilled in the corners of the lower block for spiral springs of sufficient power to keep the blocks apart.

The steel should be heated (a small gas furnace is preferable), and quickly inserted between the blocks, and pressed hard until cool enough to insure against drawing temper.

A good plan is to have two pieces in the furnace at once, and allow one to cool when the other is heating.

To draw the temper, brighten part of the piece on an emery-wheel, and then run them together with sand in a sheet-iron tumbler under which is a fire (a few gas jets are the best), until the desired color is obtained.

MELTING ZINC.—Zinc is troublesome to cast, and more troublesome when small thin molds are to be cast. Lining the mold with whiting and water, which must be allowed to thoroughly dry, will often cause the metal to fill the mold well. Burning of the zinc (oxidizing) may be prevented by covering the metal, while in crucible or ladle, with a layer of common salt, a little muriatic acid, which amounts to the same, as a coat of zinc oxide is immediately formed on the surface of the melted metal, which effectually prevents further oxidation from action of oxygen in the atmosphere. It is an improvement to keep a layer of charcoal on top of the zinc, or any other soft metal which can be melted in a ladle; the coating of oxide forms a protection against oxidation to only a certain degree, while the layer of charcoal tends to reduce the oxide again to its metallic form. Indeed, it is possible to recover lead, tin, zinc and antimony from the "dross" or oxide which gathers in the ladle. It is only necessary to melt the oxide with charcoal, salt and soda to get it again into useful shape. The dross should be powdered, likewise the salt, charcoal and soda. Mix them together and melt. The soda and salt melt into a pasty mass and the carbon unites with the oxygen of the dross, leaving the metal free but burning off the charcoal. The salt and soda act simply as flux in reducing the oxides.—*Western Machinist.*

A STANDARD CAR AXLE.—The proposition for a new standard car axle for railroad cars of 60,000 pounds capacity is being agitated by the different railroad clubs of the country. Its necessity is recognized by all, but those interested are divided on the question of size. A standard axle was agreed upon in 1873, but the increase in the weight of carloads has been so great as to render this standard untrustworthy. The sizes for the contemplated axle vary greatly, but many 7 feet 2 inches long and 6 feet 4½ inches between centers are being used with fair success in carrying heavy cars. Many favor an axle 6 feet 11½ inches long and 6 feet 3 inches between centers, saying that it is really desirable to retain the latter distance, especially in the new standard axle. It is hoped that when the Master Car-Builders' Association meets next June the members will adjust all minor differences and hair-splitting distinctions, and agree upon a standard axle which will carry not only 60,000 pounds, but be capable of standing the much heavier strain of a constantly increasing freight business.—*Age of Steel.*

CLOTHING A SHIP IN STEEL.—Two or three months or less after the completion of the "fairing," the ship is probably "in frame," and looks like the skeleton of some Brobdignagian monster that has stranded on the bank of the river. The ribs have been hoisted into position at right angles with the keel, and strung together by "rib-bands," and already there are signs of the coming subdivision by decks and bulkheads of the hollow space within. You can still see through her, however; she is like, to make yet another comparison, a great oblong wicker basket, the supple willows being represented by the network of steel. The next step is the clothing of the ribs with plates. As they reach the yard the plates are square and flat, but they are passed through rollers of various kinds, from which they issue in any shape desired—hollow like a spoon, curved lengthwise or breadthwise or diagonally, as the contour of the ship may call for. A steam or hydraulic plane smoothe them down as though they were of the softest of whitewood; another machine trims the edges as easily as a woman cuts silk with a pair of scissors. Then, suspended by iron chains, they are thrust between the jaws of a punching machine, which has a resemblance to a sinister human face with a flat nose, a long upper lip and a small chin. The jaws close upon them and bite out, ten at a time, the holes for the rivets by which they are to be fastened to the frame.—*Scribner's for April.*

THE OLDEST SPECIMENS OF IRON in existence, now known, are probably a sickle-blade found by Belzoni under the base of a sphinx in Karnac, near Thebes; the blade found by Colonel Vyse, imbedded in the masonry of the great pyramid; the portion of a crosscut saw exhumed at Nimrod by Mr. Layard—all of which are now in the British Museum. A wrought bar of Damascus steel was presented by King Porus to Alexander the Great, and the razor steel of China for many centuries has surpassed all European steel in temper and durability of edge. The Hindoos appear to have made wrought iron directly from the ore, without passing it through the furnace, from time immemorial, and elaborately wrought masses of iron are still found in India, which date from the early centuries of the Christian era.

HOW TO COPPER IRON.—It is stated in the *Metallarbeiter* that iron can be coppered by dipping it into melted copper, the surface of which is protected by a melted layer of cryolyte and phosphoric acid, the articles to be thus treated being heated to the same temperature as the melted copper. Another process consists in dipping the articles into a melted mixture of one part of chloride or fluoride of copper, five or six parts of cryolite and a little chloride of barium. If the article, when immersed, is connected with the negative pole of a battery, the process is hastened. A third method consists in dipping the articles in a solution of oxalate of copper and bicarbonate of soda, dissolved in 10 or 15 parts of water, acidified with organic acid.

BRICKLAYING IN WINTER.—In Norway, building operations are carried on without interruption during the winter, unless the temperature falls less than 14° to 18° F. The whole secret of the matter is that the Norwegians buy their lime, not slacked, but only burnt, and, like the ancient Romans, mix their mortar only in small quantities for immediate use. The bricks are kept under cover prior to use, and the upper courses of bricks which have been laid are shielded from rain or snow by means of planks and mats during the night, or whenever work is suspended. By attending to these simple precautions, building operations can be carried on through the winter, to the benefit of all concerned.

A TEST OF AXLES.—Some time ago a superintendent of motive-power of one of the Pennsylvania proprietary roads, who interested himself in making the best possible record in the economical operating of his department, concluded that steel axles were not so valuable as they were reputed to be, so he made some very careful tests of the journal wear of iron and steel axles doing the same kind of service. The journal wear per 50,000 miles was found to be practically the same for the axles of both material. As the iron axle is considerably less in first cost, it was the cheaper of the two. An old iron axle is generally regarded as more reliable than an old steel axle.—*National Car-Builder.*

IMPROVED ANNEALING PROCESS.—An improvement in the operation of annealing wire is announced. It consists in coiling the wire upon a hollow metallic core or drum, imbedding the wire or core in sand or its equivalent, surrounding a central open space, subjecting the whole to heat with the wire thus imbedded, and then allowing the whole to cool before removing the wire from the imbedding material. While cooling, the vessel is dipped intermittently into cooling liquid.

SOLDER FOR ALUMINUM to be used for the blowpipe, 10 parts silver, 10 parts copper, 20 parts aluminum, 60 parts tin, 30 parts zinc. For solder with the common soldering iron, use 95 parts tin and 5 parts bismuth, or 97 parts tin and 3 parts bismuth. The flux to be used in all cases is either paraffine, stearine, vaseline or benzine. The articles must be well cleaned before soldering, and heated just enough to make the solder adhere.

STEEL WATER PIPES are still gaining ground, and a Scotch company is now making 20 miles of such pipe for use in Mexico. The diameter is not given, but the thickness of the steel plate is 1-10 inches, and the engineers say that previous experience shows them that corrosion need not be feared. The Sydney water works have lately issued tenders for 1600 tons of steel water mains of a larger size.

ZINC, of all ordinary metals, expands or contracts the most by the application or withdrawal of heat.

IT is said that the exhibit of steam engines at the Paris Exposition will be the finest ever seen.

IT is proposed to substitute electric welding for riveting, in the manufacture of boilers.

SCIENTIFIC PROGRESS.

What is Electricity?

Prof. Pedro G Salom contributes a paper on this topic to the *Electrical World* of March 23d, which places the question on a chemical basis—reducing all electrical action to a chemical origin, as follows:

The study of the subject of electrical accumulators, a paper on which I recently presented before the American Institute of Mining Engineers, has given rise to a number of speculations as to what electricity is, and one of which is so important, if true, that I feel inclined to state it at once, rather than wait for time to make confirmatory tests of its truth or falsity. I refer to the theory of lightning.

For a long time we have had in chemistry the names of two mysterious elements or compounds or forms of oxygen called ozone and antozone, and while there may be very good grounds for the belief in the existence of these elements or substances, I have never met a chemist in my 15 years' experience who ever saw an ounce of ozone, or knew how to prepare an ounce; and as to antozone, that is still more hypothetical.

Now I have a very simple theory in regard to this matter, which I think explains all the facts, or most of them, and which enjoys the great advantage over most theories, in that I believe it can be practically proved or demonstrated. My theory is, that the molecules of water by being expanded when dissolved in the air, and reaching a still further degree of expansion by reason of the heat absorbed when in the form of clouds and in the rarefied atmosphere of great altitudes, reach a point where the well-known phenomenon of disassociation begins; and that they are broken up into their original elements, hydrogen and oxygen, or into hydrogen and hydroxyl, which is the water radical having an affinity of one, or acting, in other words, like a monad element. This I believe is the mysterious ozone, so called, and furnishes the remarkable properties that ozone is said to exhibit, viz., a superior property or ability for oxidation over ordinary oxygen.

For example, if we take two molecules of hydroxyl and combine them, we form water and oxygen, thus: $HO+HO=H^2O+O$; or oxygen in the free or nascent state which exhibits superior oxidizing characteristics.

Now let us examine what takes place in thunder-storms, on a hot day in summer, when they usually occur. At that time the air is surcharged with moisture owing to its heated condition, and a degree of expansion takes place until the water is disassociated by rarefaction and we have instead of clouds mysteriously charged with positive and negative electricity, which we know nothing about, hydrogen and oxygen, which we do know something about, or hydrogen and hydroxyl.

We also know that the latter is a very unstable body, and will take up hydrogen to complete the water molecule, or two molecules of hydroxyl will give up one atom of oxygen and thereby form the water molecule. It is also a powerful oxidizing agent, like so-called ozone, and, under certain conditions, this remarkable substance, which has been so little studied, is a reducing agent.

This can be illustrated graphically as follows:

$$HO+H=H_2O;$$
$$HO+HO=H_2O+O;$$
$$M_nO_2+2HO=M_nO+H_2O+2O.$$

We have only to assume the energy of combination of these two gases to be set free as electric energy instead of heat, in a manner similar to the energy of combination of the elements of a galvanic battery. The molecules of gases, in other words, arrange themselves like little batteries, and we can assume by their polarization an almost indefinite number of them in series accounting for the high potential in lightning up to thousands of volts if necessary, and at the same time a relatively small amount of current, owing to the fact that the actual amount of water produced, or involved in the discharge, is really comparatively small. When we consider that E. M. F. derived from the chemical affinity of a single atom of oxygen for two atoms of hydrogen is 1 5 volt, or is equal to 7144 foot-pounds, we have all the necessary data to account for the gigantic force and destructiveness of lightning; we know, moreover, that after a very severe stroke of lightning, the rainfall for a short time is heavier.

Now to liberate .00001012 gramme of hydrogen requires one coulomb or one ampere-second; consequently one gramme of hydrogen will require 97,847 coulombs, and 454 grammes or 1 pound will require 44,422,538 coulombs, or 12,340 ampere-hours at 1 volt, or 18 electrical horse-power hours, or 25 640,000 foot-pounds.

One hundred cubic feet of air at 100 degrees Fahrenheit will hold a little over .25 pound of water vapor. Therefore, 400 cubic feet will hold 1 pound, and as water contains 11 per cent of hydrogen, it would take about 4000 cubic feet to furnish the hydrogen necessary to account for the energy.

The assumption of the existence of the hypothetical ether is unnecessary, and I believe mathematically unsound. It is the old phlogiston theory of Stahl bobbing up serenely after having been laid to rest for over 100 years by the brilliant discoveries of Lavoisier. Moreover, it does not help us in the least. The old question still remains. If ether is necessary for the conduction of light, heat and electricity, what is it that conduces between the atoms of ether? Surely the philosophers don't mean to tell us that ether is absolutely solid, or, in other words, not made up of molecules or atoms. If it were, where would poor, ordinary matter, which we so much despise, but which in reality we know so little about, come in? If space is solid ether, how can there be any room for matter? Is it not better to try to find out something more about the things we have with us than to invent mysteries absolutely inconceivable?

The above theory, in my judgment, establishes electricity on a thoroughly chemical basis. No ether, no mysterious fluids of positive and negative character, no *immaterial material* such as phlogiston or caloric (merely names invented to conceal our ignorance), is necessary any longer to account for the phenomena. Therefore, I can repeat more forcibly than ever the definition which I gave in a short lecture at the Franklin Institute two years ago, that "electricity (or perhaps more properly speaking, E. M. F.) is the mechanical expression of chemical affinity."

This is a subject of such far-reaching importance and of such a high scientific value that it would be presumptuous for me to indicate, even if I were able, the great questions involved in a true understanding of the subject.

WHAT WOULD HAPPEN?—In reply to the question, "What would happen if the plane of the earth's equator were coincident with that of the earth's orbit round the sun?" a writer says: Day and night would be equal all the world over. There would be no seasons in any latitude. The sun would always appear to travel in a vertical circle directly over the equator, and at either pole he would be seen bowling round the horizon every 24 hours. Daylight would there be perpetual; the sun would never set at all; for though his actual relative position would be such as to dip half below and rise half above the horizon, the effect of refraction would be to raise his visible orb well above the horizon altogether. All over the world one day would be as good as another, or as bad, for sowing or reaping. No granaries, no ricks, no stores of any kind of food would be required, as a daily succession of crops of anything and everything sowable and reapable in any latitude would be attainable. Even similarly successive crops of fruit might be obtained by a selection of trees and bushes. The requirements of human beings would be curiously changed, and the political economy of Adam Smith and Stuart Mill would be quite as absurd as Mr. Ruskin believes it to be; for the withdrawal of all the necessities for saving and storing would remove the chief necessity for capital and thrift.

NEPTUNE AND ITS SATELLITE.—M. Tisserand has presented a report to the Paris Academy of Sciences, concerning some remarkable observations of the satellite of the planet Neptune, which was discovered in 1847. The angle which the plane of the orbit of this satellite made at that date with the ecliptic was about 30°, but this angle has now been increased by at least 6°. The satellite moves round its principal in an opposite direction to that usually followed by other satellites, so that a question might be raised whether in course of time this variation in the inclination of the plane of its orbit might not end in its movement around its principal becoming normal. M. Tisserand shows that this variation of inclination was due to the oblate or flattened condition of Neptune at its poles and that it will complete its limit within a period of 500 years, at the end of which time it will again be as it was in 1847.

THE GREATEST OCEAN DEPTH.—The greatest known depth of the ocean is midway between the Island of Tristan d'Acunha and the mouth of the Rio de la Plata. The bottom was there reached at a depth of 40,236 feet, or 8¼ miles, exceeding by more than 17,000 feet the hight of Mount Everest, the loftiest mountain in the world. In the North Atlantic ocean, south of Newfoundland, soundings have been made to a depth of 4580 fathoms, or 27,480 feet, while depths equaling 34,000 feet, or 6½ miles, are reported south of the Bermuda islands. The average depth of the Pacific ocean between Japan and California is a little over 2000 fathoms; between Chili and the Sandwich islands, 2500 fathoms; and between Chili and New Zealand, 1500 fathoms. The average depth of all the oceans is from 2000 to 2500 fathoms.

GELATINE IN VARNISH.—A varnish made with alcohol will get dull and spongy by the evaporation of the alcohol, which leaves water in the varnish, as all commercial alcohol contains water. It is, therefore, says the *Carriage Monthly*, advisable to take a thin sheet of gelatine, cut it into strips and put it into the varnish; it will absorb in the thin sheet most of the water, and the varnish can be used clear and bright till the last drop. The gelatine will get quite soft. It can then be taken out and used again.

GREAT EARTHQUAKE DISTURBANCES.—According to M. Blavier's theory, the great earthquake disturbances of 1755, 1884 and 1887, are to be associated with the abnormal accumulations of ice about the north pole. He supposes such accumulations to have caused a deflection of the Gulf Stream away from Europe, producing great climatic changes and a slight disturbance of equilibrium in the sea bottom, followed by a possible local fracture along the line of least resistance.

Good Health.

Why Teeth Decay.

Microscopic Germs or Bacteria at the Seat of the Trouble.

Decay of the teeth (caries) is exceedingly common, especially so among civi ized people. The lack of power to resist this disease may be due to the depression of vital vigor through overtaxing the nervous system or through sedentary habits and luxurious living. In this, as in other matters, there are inherited tendencies, and the children of those whose teeth decay early themselves suffer the same evil.

But what is the immediate cause of dental decay? A paper on the subject was read by Dr. Geo. S. Allen, of New York, before a meeting of the Dental Union, lately held in Boston.

According to this paper the credit of solving the question belongs to Dr. W. D. Miller, an American residing in Berlin, Germany. The solution is found in the germ theory, which has already settled the origin of so many infectious diseases.

The microscopic germs, which are called bacteria, the smallest of organized beings, so small that it takes 100,000 of them placed lengthwise to measure an inch, belong to the plant family. They multiply both by division and by the formation of spores. The spores, which correspond to seeds, have great vitality, and are unaffected by the temperature that would destroy the parent plant. The multiplication by division is exceedingly rapid.

Thus the total eradication of the germs is almost out of the question, and in even a short time, if the pest be neglected, it becomes difficult to limit the harm they can do. That harm may be effected either by the growth of the bacteria at the expense of the cells of the body, or more probably, perhaps, by developing a poison in their waste products.

It must be remembered, however, that many kinds of bacteria are perfectly harmless, while it is possible that some aid in the vital processes of the organism.

The mouth is infested by several forms of innocent bacteria. The saliva is never free from them. Therefore, in order to ascertain if dental caries is due to bacteria, most rigorous tests were necessary. The bacteria must be found in the decayed matter of the teeth; be isolated from every other kind; cultivated outside of the body, and the pure cultivation must produce a similar caries when introduced into a healthy tooth, and this caries must show the same form of bacteria.

Dr. Miller's experiments have conformed to these tests. He found bacteria filling the tubules of the decayed teeth; obtained pure cultures from them, and, placing the latter in tubes with pieces of sound teeth, the microscope in from two to four weeks showed a similar caries, and the tubules distended with similar bacteria.

The Length of Life.

Life insurance men have made of the question of longevity almost a determined science, with an ample array of figures and rules. According to these, the average man who has reached the age of 60 has still a little less, and the average woman who has reached the age of 60 a little more, than 14 years to live. But the expectation of life does not, relatively, diminish with the advance of years, for at 80 the man's chance is somewhat less, and the woman's somewhat more, than five years and a half. According to the English standards, the persons who live longest are members of the clergy, while in other pursuits longevity ranks in the following order: Farmers, merchants, soldiers, clerks, teachers and physicians. The death-rate among the clergy of the Established Church of England is exceptionally low, being, in the years of active clerical service, only 10 in 1000 of population, whereas that of the English Catholic clergy is 50 per cent higher. The figures of the insurance companies, which are ample regarding every point involved, show that, the age of 50 passed, the expectation of life is more than twice as great for the temperate as for the inebriate, the proportion being as seven to three. The proportion of the rich as compared with the poor, over 70, is about four to one, and it is generally higher among women than among men. We suppose there is no country of the world where the science of long life, accompanied with good health, unimpaired mental faculties, good digestion and great activity, is better understood than in France, and there, of 1000 persons born, 120 reach the age of 70, and the percentage continues to be high until 85 is passed. The nervous, exciting, restless life of most Americans is not conducive to extreme longevity, and the steadily large immigration of those who have reached the years of manhood in other lands as emigrants tends to greatly reduce the standard of longevity in this country; but the tables of American insurance companies show that it is steadily rising. Should this increase continue, it may not be many years before the rate here will compare favorably with what long experience and repeated proofs have shown to be the normal rate in other lands.—*N. Y. Sun.*

How to be a Good Nurse.—Six things, says a doctor writing on the subject, are necessary to a good nurse; Strong, equable health; sound nerve; minute observation; a retentive memory; habits of neatness and cleanliness, and a calm, collected mind. A nurse must never disregard her health, because it is essential to her own well-being, and because, too, attendants on the sick should always be cheerful and hopeful. Sound nerve is often a matter of training, but its root lies in unselfishness. Any one who, in an accident or operation, forgets self in the desire to aid others, will not be troubled by trembling or fainting. The faculties of observation and retentiveness of memory can be developed by having interest in the work strong enough to make the nurse careful and patient in her observations. A calm mind is generally the result of organization. If a nurse has arranged her day's work beforehand, if she keeps everything punctually to this arrangement, and if everything needful is neatly disposed, she is not likely to be discovered in bustle and confusion at any time. The nurse should, furthermore, be mindful that she is under the doctor, and should respect and obey his directions, even if she differs in opinion from him. It is extremely important that those who are sick and suffering should be treated with unfailing gentleness and patience; nothing can ever excuse a nurse for losing her temper with her patient. No duty is too little or trifling for her attention, and no work that is for the good of the patient can be degrading. It is further a good rule never to approach a case fasting, but always have a good meal before going on duty. —*Science Monthly.*

The Massage Treatment.—Fe jean doctors are said to have great faith in massage, which they have practiced from time immemorial, and have taught to the Samoans and the Tongans. The rubbing and kneading of the affected part is sometimes continued for hours, stimulating the circulation and relieving the pain.

European Health Resorts.—Some of the "cures" at a European resort are mineral-water cure, grape cure, whey cure, cold-water cure, massage cure, pine-needle baths, Russian, Roman, Irish, mud, steam and electric baths. All ills are met by "cures."

Smothering Infants.—An English medical journal declares that the number of infants smothered to death in England by half-tipsy parents, between sunset on Saturday and sunrise on Monday, exceeds the mortality of any other night in the week.

To Fumigate a Room.—The simplest way to fumigate a room is to heat an iron shovel very hot, and then pour vinegar upon it, drop by drop. The steam arising from this is a disinfectant. Doors or windows should be opened that it may escape.

Useful Information.

A Substitute for Coffee.

A discovery of a curious nature has been made recently in the island of Reunion, and is considered by alarmists a serious danger to the coffee trade. The island in question abounds in the wild orange. This plant produces a fruit which in its first stages is of a green color, which is gradually metamorphosed into something approaching blue, while the first stage of maturity and ripeness is signalized by a purple tint. Though its possible utility from a commercial standpoint has been hitherto wholly unknown, it was, for some unstated purpose, recently subjected to a certain test, by which it has been discovered to possess every quality which could be required in an excellent substitute for coffee. It is equal in its flavor to the time-honored berry, even in its best condition, and the small cost of its production will place it within the reach of many for whom ordinary good coffee is an expensive luxury. The colonial Government of Reunion is examining the facts of the case, and 24,000 acres in the most elevated parts of the island are sold to be devoted henceforth to the cultivation of the wild orange. A return of 3 000,000 kilogrammes is expected annually. One result of the discovery will be in all probability a tremendous fall in the chicory trade. Two million kilogrammes of this wholesome substance are annually blended with French coffee, which is now imported in enormous quantities into England. Mussaenda is the curious and not euphonious name which has been conferred on the produce of the wild orange, and it is confidently declared that it can compete with pure coffee, and when mixed therewith it improves it in a marked manner, alike in taste and fragrance.

Secrets Read in the Face.—A man's occupation or condition has a good deal to do with his facial expression, remarks the *Herald of Health.* Intellectual pursuits, like the studies of the scholarly profession, when coupled with temperate and moral habits of life, brighten the face and give a person a superior look. Magnanimity of nature, or love of studies and art, will make a bright, glad face; but, contrary to this, a man may have a face that does not please anybody, because of a love of self to the exclusion of all others, notwithstanding his learning and worldly shrewdness. Soldiers get a hard, severe look; overworked laborers constantly look tired; reporters look inquisitive; mathematicians look studious; judges become grave, even when off the bench; the man who has had domestic trouble looks all broken up. An example of the ludicrous side of this subject is to see a third-class lawyer stalking around a police court looking as wise as an owl. The business makes the face, I say. There's the butcher's face, the ministerial face, the lawyer's face, the doctor's face, the hoodlum's face, all so distinct each from the other and singly, that I seldom fail to recognize those callings showing through the faces. And what city boy cannot recognize a genuine farmer on the street, as a farmer, the moment he sees him?

Why Paper Becomes Brittle.—A German writer in *Papier Zeitung* recently gave a description of certain observations on the above subject, which the writer had made extending over a period of ten years. His observations led to the conclusion that neutral or basic sulphate of alumina, which is often used in the manufacture of writing papers, exercises no decomposing influence on paper at ordinary temperatures, whether "size" be present or not, but that sulphate of alumina has a strongly caustic action if chlorides—such as those of sodium (common salt)—and calcium be present, especially at high temperatures. In this case an injurious action on the paper arises from the formation of aluminium chloride, or free hydrochloric acid, which acts by abstracting the elements of water from the cellulose. The advice given by the author (Herr C. Wurster) is, therefore, that the manufacturers should endeavor to remove, as far as possible, by washing, from the fabric any sodium or calcium chloride resulting from the bleaching powder. It is, accordingly, not advisable to kill the bleach by anti-chlor, without subsequent washing. The author concludes, from these considerations, that the testing of paper should include a qualitative or quantitative examination of the chlorides present, which have hitherto been looked upon as being quite harmless.

Drowned Bodies and a Loaf of Bread.—There is a curious and widespread belief that the whereabouts of a drowned man may be ascertained by floating a loaf of bread down a stream, when it will stop over the spot where the body is. A curious account of a body thus recovered near Hull appeared some years back in the *Gentleman's Magazine.* "After diligent search had been made in the river for the child, to no purpose, a two-penny loaf, with a quantity of quicksilver put into it, was set floating from the place where the child was supposed to have fallen in, which steered its course down the river upward of half a mile, when, the body happening to lie on the contrary side of the river, the loaf suddenly tacked about and swam across the river and gradually sank near the child, when both the child and the loaf were brought up with the grapplers ready for the purpose." A correspondent of *Notes and Queries* maintains that it is a scientific fact that a loaf and quicksilver indicates the position of the body, as the weighted loaf is carried by the current just as the body is. This practice, too, prevails on the continent; and in Germany the name of the drowned person is inscribed on the piece of bread, while in France loaves consecrated to St. Nicholas, with a lighted wax taper in them, have generally been employed for that purpose.

The Future of China.—Baron Richthofen, in describing the northwest of China, says that the Shansi district is one of the most remarkable coal and iron regions in the world, and he estimates that at the present rate of consumption the coal of this district would supply the world for thousands of years to come. It is claimed by some writers that Shansi, when more thoroughly explored, will bear away the palm from Pennsylvania, whose 20,000 square miles of coal land have been heretofore considered as the greatest single deposit in the world. Richthofen says further that this coal can be very easily and cheaply extracted on a large scale, and that iron ore of excellent quality is found in quantities in the immediate vicinity of the coal fields. Be this as it may, mineral wealth is abundant, and when it comes to a question of labor, the Chinese can furnish this to an almost limitless degree, and recruit it from a class that is naturally patient, skillful and content with small gains.

A Race of Giant Rats.—Stonington, Conn., it is stated, has a new kind of a rat which stole a ride in a schooner that recently came from Cape Horn. Twenty or 30 of them came in the vessel as samples and to inspect this country to see whether it will do. They landed at once, fell in with the New England seaboard rats, got acquainted, and are now on good terms with them. The Cape Horn rat is an entirely new thing in North America. He has very long ears, an extremely long tail, and in every way is built on the liberal plan peculiar to the Patagonian fauna. It was a surprise to Stonington that he fellowshiped with the native Norway rat, as no other living thing will associate with that animal, which drove the old-fashioned black rat that was indigenous there 40 miles back from the coast.

Water-Pipe Discharge.—In a paper read before the Royal Society (England), Henry Hennessy, F. R. S., says the maximum discharge of water through a pipe of circular section, when the head is due only to the inclination of the pipe, is not when the pipe is full of water, but when filled to about nineteen-twentieths of its diameter.

The New Land Law.

The Register of the Land Office has received a copy of the new Act of Congress, approved March 2, 1889, affecting settlers on public lands. It is as follows:

Be it enacted, etc., Section 1. That from and after the passage of this Act no public lands of the United States, except those in the State of Missouri, shall be subject to private entry.

Sec. 2. That any person who has not heretofore perfected title to a tract of land of which he has made entry under the homestead law may make a homestead entry of not exceeding one-quarter section of public land subject to such entry, such previous entry or filing to the contrary notwithstanding; but this right shall not apply to persons who perfect title to lands under the pre-emption or homestead laws already initiated; provided that all pre-emption settlers upon the public lands whose claims have been initiated prior to the passage of this Act may change such entries to homestead entries and proceed to perfect their titles to their respective claims under the homestead law notwithstanding they may have heretofore had the benefit of such law; but such settlers who perfect title to such claims under the homestead law shall not thereafter be entitled to enter other lands under the pre-emption or homestead laws of the United States.

Sec 3. That whenever it shall be made to appear to the Register and Receiver of any public land office, under such regulations as the Secretary of the Interior may prescribe, that any settler upon the public domain under existing law is unable by reason of a total or partial destruction or failure of crops, sickness or other unavoidable casualty, to secure a support for himself, herself, or those dependent upon him or her, upon the lands settled upon, then such Register and Receiver may grant to such settler a leave of absence from the claim upon which he or she has filed for a period not exceeding one year at any one time, and such settler so granted leave of absence shall forfeit no rights by reason of such absence, provided that the time of such actual absence shall not be deducted from the actual residence required by law.

Sec. 4. That the price of all sections and parts of sections of the public lands within the limits of the portions of the several grants of lands to aid in the construction of railroads which have been heretofore and which may hereafter be forfeited, which were by the Act making such grants or have since been increased to the double minimum price, and, also, of all lands within the limits of any such railroad grant, but not embraced in such grant lying adjacent to and coterminous with the portions of the lines of any such railroad which shall not be completed at date of this Act, is hereby fixed at $1.25 per acre.

Sec. 5. That any homestead settler who has heretofore entered less than one-quarter section of land may enter other and additional land lying contiguous to the original entry, which shall not, with the land first entered and occupied, exceed in the aggregate 160 acres without proof of residence upon and cultivation of the additional entry; and if final proof of settlement and cultivation has been made for the original entry, when the additional entry is made, then the patent shall issue without further proof; provided, that this section shall not apply to or for the benefit of any person who at the date of making application for entry hereunder does not own and occupy the lands covered by his original entry; and provided, that if the original entry should fail for any reason, prior to patent, or should appear to be illegal or fraudulent, the additional entry shall not be permitted, or if having been initiated shall be canceled.

Sec. 6. That every person entitled, under the provisions of the homestead laws, to enter a homestead, who has heretofore complied with, or who shall hereafter comply with the conditions of said laws, and who shall have made his final proof thereunder for a quantity of land less than 160 acres and received the Receiver's final receipt therefor, shall be entitled under said laws to enter as a personal right, and not assignable, by legal subdivisions of the public lands of the United States subject to homestead entry, so much additional land as added to the quantity previously so entered by him shall not exceed 160 acres; provided, that in no case shall patent issue for the land covered by such additional entry until the person making such additional entry shall have actually and in conformity with the homestead laws resided upon and cultivated the lands so additionally entered, and otherwise fully complied with such laws; provided, also, that this section shall not be construed as affecting any rights as to location of soldiers' certificates heretofore issued under Section 2306 of the Revised Statutes.

Sec. 7. That the "Act to provide additional regulations for homestead and pre-emption entries of public lands," approved March 3, 1879, shall not be construed to forbid the taking of testimony for final proof within ten days following the day advertised as upon which such final proof shall be made, in cases where accident or unavoidable delays have prevented the applicant or witnesses from making such proof on the date specified.

Sec. 8. That nothing in this Act shall be construed as suspending, repealing or in any way rendering inoperative the provisions of the Act entitled "An Act to provide for the disposal of abandoned and useless military reservations," approved July 5, 1884.

The Santa Cruz *Surf* is authority for the statement that a new lumber line is soon to be built from Corvalitos to Moss Landing. The proposed line will start from a point in the bay shore, about half a mile below Capitola, and will extend up the easterly side of the Soquel canyon, and into an immense timber belt, owned by private parties who are behind the scheme. Where the line joins the Southern Pacific a large sawmill is to be built. The road will be operated in connection with the Southern Pacific. Surveys have been made, right of way procured and the line located for the greater part of the distance. It will be a broad gauge.

Sawdust is being used as fuel in factories and mills on this coast to a greater extent than ever before, owing to the high price of wood and coal.

Passing Events.

Reports from all over the State give the outlook as most encouraging for this year's season. Crops are expected to be unusually large, owing to the very favorable climatic conditions.

The quartz industry of California is now very prosperous. More quartz mines are being worked than ever before in the history of the State. Those which were known but which would not pay 20 years ago are now profitable.

A new 120-stamp mill for an Alaska mine is the third of the same size sent from here to that Territory. The quartz deposits there are of low grade, but very large, being, in fact, almost quarries. There is an immense area of territory in that region yet unprospected.

NOTWITHSTANDING the fact that all the necessary stores have been placed aboard the cruiser Charleston and a captain appointed for her trial trip, the date of that event has not been determined upon.

THE executive committee having in charge the centenary celebration of Washington's inauguration are making preparations for a monster demonstration on April 30.

Marine Engines.

It is pretty evident that the success of the warship of the future will depend just as much on the power of her engines as on the form or style of the vessel itself. The armament is, of course, a very important feature, but if the engines cannot properly bring the vessel and armament where it is wanted, and at the proper time, neither vessel nor armament will amount to much.

The navy now depends entirely on steam, but steam must be properly used and there must be plenty of it. We have been for a long time putting "nine-cat power" engines into big vessels which have had difficulty in getting out of their own way. The navy has by no means kept pace with the merchant marine in the matter of speed or power. Probably the trouble has partly been that the navy has stuck to old designs and old ideas too long. It has not been as progressive as should have been the case.

In addition to the sorrow which the American people feel at the loss of so many lives during the hurricane at Samoa, there is also a feeling of disgust that our ships were not sufficiently provided with power to enable them to escape from the dangers that finally caused their destruction. This feeling would have been lessened had it not been apparent that other ships were so provided and escaped. One vessel, the Calliope, steamed out of the dangerous anchorage in the teeth of the hurricane and took to the open sea, escaping all damage or loss of life.

This vessel was provided with most powerful modern engines and even then could make but half a knot an hour against the wind and sea. Had the engines been a trifle less powerful, she could have made no headway and would have gone astern and to destruction with the rest. Her commander took chances; but he would not have dared to take them had he had less confidence in his steam-power. Having this confidence—not misplaced—he succeeded in saving his valuable ship and crew, where others lost theirs.

There is a lesson in this that the American people will not forget, and it is sure that the officials who have such things in charge will not be excused when vessels are designed which have less power than they should. In these days of advanced steam-engineering knowledge there is no excuse for equipping our Government vessels with poor engines or other machinery. If there is not sufficient talent in the Naval Department to produce what is necessary and proper, it should be compelled to call upon the skilled civilians to design, as they already construct.

Here, near as we are to a Government navy-yard, those familiar with nautical matters hear more or less to the detriment of the steam machinery of Government vessels. The men-of-war have poor boilers or engines that are constantly breaking down or coming to grief in some way, in a manner that private individuals would not stand for a moment, and would see remedied at once. The officers of the vessels seem powerless to effect a change and use the machinery under silent protest. It is time a change should be made for the better. Government engines should be better if possible than those of private owners, not worse, for expense is no object. The Government steam machinery has come to be a laughing-stock all over the country.

Clarke Russell, the best writer on sea topics that ever lived, tells a story of a ship-owner that habitually overloaded his ships, notwithstanding the remonstrances of his officers. He always contended that a ship could not be overloaded. Finally he had to make a short voyage in one of his own steamers, which was loaded in the usual way. Then he had an experience which he never forgot. He feared for his life for days, though the weather was by no means as bad as might have been the case. It resulted in a complete change of his system of loading. It is a pity that some of the contractors or designers, or whatever class of persons are responsible for our weak-engined ships, were not on board in that Samoan hurricane instead of the poor fellows who were sacrificed to their ignorance, stupidity or greed. Some of the arm-chair critics at Washington now presume to contradict the officers who were in the hurricane as to the facts and causes of the loss, by which it would appear that instead of feeling grateful at having defects of design pointed out after experience, they prefer to justify their lack of practical knowledge. It is just such senseless official stupidity as this which gives us poor vessels in the navy instead of good ones.

The El Paso Ore Works.

Some five years since Mr. Robert S. Towne established in El Paso a sampling works, under the name of the "Mexican Ore Company." In its incipiency the object of these works was to draw from Mexico a supply of the high-grade rebellious ore for which that country is noted. The sampling works were run in conjunction with the "Kansas City Smelting & Refining Company."

The business of the Mexican Ore Company increased to such proportions that Mr. Towne and three other gentlemen united in the construction of the El Paso plant. Quite recently the Kansas City corporation has united with the El Paso outfit, forming one company, with the central offices at Kansas City.

The El Paso plant is located on the American bank of the Rio Grande, some 2½ miles above El Paso. The works are so located that the Atchison, Topeka & Santa Fe and Southern Pacific railroads run through the yard. The smelting company own some 1300 acres in the immediate vicinity of the works.

Switches from the railroad deliver the ore directly into the sampling-house; from here it goes either to the furnace-bins or to the roasting-furnaces. The roasting-plant consists of four four-hearth reverberatory furnaces, with a capacity of 12 tons per day each. There are five smelting-furnaces of the "Rachette" type. The inside dimensions of the furnaces are 36 by 100 inches at the tuyere. The furnaces are all water-jacketed; the combined capacity is 200 tons of ore per day.

There are employed in and about the works some 300 men, principally Mexicans; the pay-roll amounts to about $14,000 per month. About two-thirds of the ore smelted comes from Mexico, the remainder coming principally from Arizona and New Mexico. The works are under the general management of Mr. Henderson, Mr. Allen being the metallurgist.

A New Ore-Feeder.

George Johnson of the Little Nelly mine, Shasta, Shasta Co., has just received, through the MINING AND SCIENTIFIC PRESS, a patent on an improved ore-feeder. The operation of this feeder is as follows: The ore passes down through the mouth of the hopper and rests upon a horizontal cylinder. The rotary motion of the cylinder carries the ore against an inclined scraper or feed-flange, which serves a purpose similar to that of the thread of a screw, carrying the ore forward on the cylinder and directing it into a discharge plate at the end. The ore is kept on the cylinder by a guide flange on the other side. But a small portion of the ore at a time can fall upon the cylinder, and the cylinder being horizontal, the ore cannot run down it by gravity to any extent, but must be fed off directly by the scraper flange. This results in a uniform and regular feed, and as but a stated quantity of ore can come from the hopper, the service to the cylinder is regular, and but small power is required to impart to it the necessary movement; nor is there any liability to choke or clog. Having the cylinder horizontal, the inventor finds to be advantageous in preventing the ore from rolling down over and from it, as it would have a tendency to do if the cylinder were mounted at an inclination. Being horizontal, the feed is wholly dependent upon being carried against the fixed scraper, and therefore is more uniform in its passage from the hopper (for only a certain amount can come from the hopper on to the horizontal cylinder) and in its discharge from the cylinder.

IT is said a Japanese line of steamers will shortly run to the Pacific Coast in opposition to the Pacific Mail. Agents have been appointed to make arrangements with the various republics, and are already in possession of several concessions.

THE Nanaimo *Courier* says: Owing to the accumulation of bad air in No. 3 mine, Roslyn, Wash., it has been shut down. This mine has been employing negroes exclusively, and about 200 of them are thereby thrown out of employment.

Foundry Notes.

The Risdon Iron Works are now running to their full capacity, especially in the boiler-shop, where there is enough work to keep it going for the next six months. Superintendent Moore reports business unusually brisk. The large boilers for the steamship Australia, the heaviest ever built on this coast, have been finished, and work is now under way getting the ship ready to receive them. In addition to their main work, they have just contracted for a 120-stamp mill for the Alaska Gold-Mining Company of Alaska Territory, to be run by steam-power and to contain all the latest improvements, this making the third 120 stamp mill built by the Risdon for Alaska.

The Bryan roller quartz-mill, which is a specialty at these works, is selling very rapidly. They have disposed of at least two dozen within the past month and have orders in hand for 14 or 15 more. They are going to all parts of Mexico, Australia and British Columbia, and give universal satisfaction wherever sent. Quartz operators should examine the Bryan mill, which has many features to recommend it.

Pelton Water-Wheels.

The Pelton Water-Wheel Co. reports a very active business and the demands for their wheels covering a very wide extent of country. The extraordinary results obtained from them under all ordinary conditions, as well as under exceptionally trying ones, as in the Chollar shaft on the Comstock, where they are working under a head of over 1600 feet, is attracting much attention, not only in this country, but in foreign parts as well.

Among the companies recently supplied with wheels are: The Roaring Fork Electric Power Co. of Aspen, Colorado, to whom six were recently sent to enlarge their plant, two having been in use for the past year; one to the Revenue Tunnel Co. of the same place; one to the Adams mine at Rico, Colorado; four to the North Banner mine and four to the Pittsburg mine, Grass Valley; two to the Golden Queen mine and one to the Gold Bank mine in Butte county; one to the Hathaway mine in Placer county; two to the Sierra Nevada Land and Water Co. and one to the Gigmag Gravel mine in El Dorado county; one to the Calaveras Consolidated Mining Co. and four to the Utica mine, Calaveras county; two to the Eureka Con. mine and one to the Golden Gate mine, Tuolumne county; eight to the Amador mine and two to the Kennedy mine, Amador county; one to the Tiger mine, Canyon Creek, Idaho; one to the Central American Reduction Co., Honduras, C. A.; one to the Olancho mines, Honduras, C. A.; one to the Baker flour-mills, Charlemont, Mass.

Most of the above, it may be stated, are large-sized wheels, calculated to develop from 50 to 75 and 100 horse-power each.

ELECTRICAL SOCIETY.—At the last meeting of the California Electrical Society the subject of the evening, "Electric Motors and the Electrical Transmission of Power," was opened by a talk, illustrated with blackboard diagrams, by J. L. Jayne of the Sprague Electrical Company. A more perfect system for the economical subdivision of a high voltage among small, efficient and harmless motors was predicted for the near future. President Keith followed, and spoke forcibly of the crude and wild ideas of electric possibilities which are current. On the utilization of Niagara by electric transmission, he said it was easily demonstrable that under present conditions, the first cost of a plant and cable to transmit 1000-horse power even 30 miles, to Buffalo, would be so great that the interest upon it would more than pay for the production of the same power from coal in the steam engine.

ARIZONA MINE SOLD.—Claflin & Co. of New York have purchased the Yellow Jacket gold mine of the Oro Blanco District, 40 miles south of Tucson, for $20,000. The final payment of $10,000 has been made on the Ploma lead and silver mines of the Tyndal District, 60 miles south of Tucson.

THE Southern Pacific Company has closed the bar at its mole at Oakland Point, and those in the eating-houses along its lines.

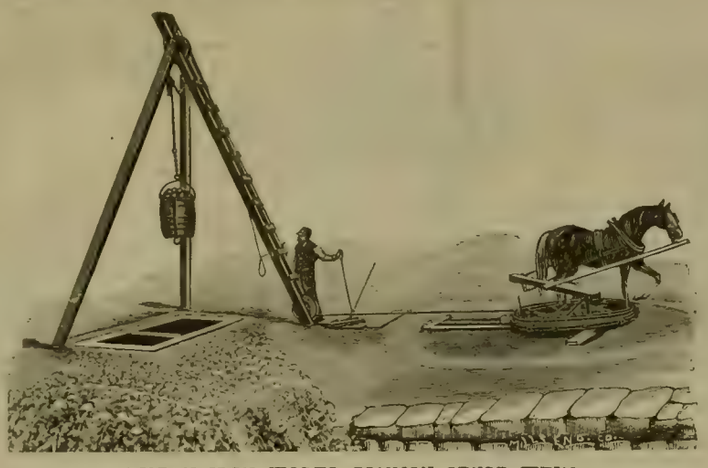
MONTEREY expects, as soon as a suitable road is built, to get the bulk of her fuel from the Sur Chiquito mines.

Lodes on the Comstock.

In the "Local Markets" and also in the "Mining Share Markets," the MINING AND SCIENTIFIC PRESS has consistently advocated the theory that lying west of the Comstock lode there were other important valuable lodes, and now we are pleased to see that the Virginia City papers are coming to the front in advocacy of this position, which begins to lose its look of theory and assume that of an actual fact. There can be no doubt but the work in West Con. Virginia did much in developing the two-lodge theory which has been still further strengthened by the developments west in Hale and Norcross, Con. Virginia and Best and Belcher, more particularly in the former. The latest improvement in the Hale and Norcross is reported to be 700 feet west of any former development, besides being of a different formation. While the MINING AND SCIENTIFIC PRESS is well pleased with its expressed views on the Comstock being substantiated by the work now going on, yet we fail to see the justice of some of the daily papers advocating the extension of the Sutro tunnel further into Mt. Davidson, the expense for which is to be borne by the leading mines on the Comstock lode. Sutro tunnel should be extended and work begun at an early day, but there can be no good reason why such mines as Hale and Norcross, Savage, Best and Belcher, Con. Virginia, Ophir and others on the Comstock lode should bear the expense. The Tunnel Company should prosecute the work and make similar arrangements for royalty with the mines located west as it has with those now paying royalty on all ores extracted and milled. The work now being done in the mines has demonstrated the richness of the vast ore bodies lying west of the Comstock lode, and has also shown the importance of extending the tunnel still further into Mt. Davidson, and demonstrating beyond the question of a doubt its richness, besides laying at rest the theory that no valuable mineral-bearing lode lies west of the Comstock.

In running the Sutro tunnel the company cut through several distinct and important lodes. These lodes are parallel with and have about the same dip as the Comstock, but their extent and value have not been fully determined, although one, the Brunswick or Occidental, is reported by the United States Geological Department to be quite large, and is liable to prove by extensive exploration work to be as rich in valuable mineral ore as has the Comstock. As laid down in Rose's map of the Comstock mines and Sutro tunnel, published in 1878, the tunnel cut through six lodes before reaching the Comstock. They were passed through in the following order: Great Flowery, Silver Star or Bella Union, Brunswick or Occidental (which is also called Monte Cristo), Solferino, Reno and the East lode. Rose's map also shows that west of the Comstock there are two lodes, but well informed mining engineers claim that there are four, perhaps five. This can only be proven correct by extending the Sutro tunnel, but that there is one, and perhaps two, the work to the west in the leading mines on Comstock, and also that now going on in West Con. Virginia, clearly proves; yet its extent and richness time can only show, but that it is proving to be more important than ever before conceived is now an admitted fact.

In this connection, it may not be out of place to state that persons who are reputed to be well informed on the Comstock aver that moneyed men are picking up titles to as many of the claims or mines located west of the Comstock lode as they can possibly secure.



RISDON IRON WORKS COMMON SENSE WHIM.

Salmon-River Gold Mines, Idaho.

[Written for the PRESS by CHAS. F. BLACKBURN.]

In the Eureka mining district, Lemhi county, Idaho, is located the Annie gold lode, a large contact vein of quartz that shows well and is without doubt a bonanza.

Herewith is given a geological chart of a section of the lode showing the adjacent formation and dip of vein.

The Annie is a porphyry-slate contact lode, striking north and south, and dips west 40° directly into the mountain range. In the chart, No. 1 represents the Annie gold lode; *A* is porphyry (footwall); *B*, chloritic talc slate (hanging-wall); *C*, block slate and gneiss; *S*, Salmon river.

The Annie gold lode is a well defined vein showing a continuous outcrop for several thousand feet. The ore body is six to seven feet in width, consisting of a fine sugary or agate-grained free-milling gold quartz that will sample $10 to $30 per ton in gold. Some of the ore, a brown honey-combed stuff, will go over a thousand dollars per ton. According to the way the quartz prospects, it will all pay to mill. It is difficult to get ore from the vein that will go less than $10 a ton.

The quartz contains very little sulphurets, and but very little is looked for until water-level is reached, which will be from 500 to 800 feet or more below the croppings, owing to "canyon drainage" near by. Several canyons cut through the lode, and one on the north, at north end of the Red Bird extension, has eroded, or cut down into the formation, to a depth exceeding 2000 feet below the Annie croppings. The property is splendidly situated for tunnel development. There are several extensions located on the Annie—the Red Bird on the north and Katie and Comet on the south. Considerable work in the way of tunnels and open cuts has been done on the property, and all the work in ore. Thousands of tons of quartz are in sight, but the owners are unable to put on a mill and develop the property. The formation is permanent, and the lode showing such a long outcrop, is bound to go down. The development of this gold lode is bound to prove a financial success, from the fact there is so much good ore exposed that failure is practically a geological impossibility.

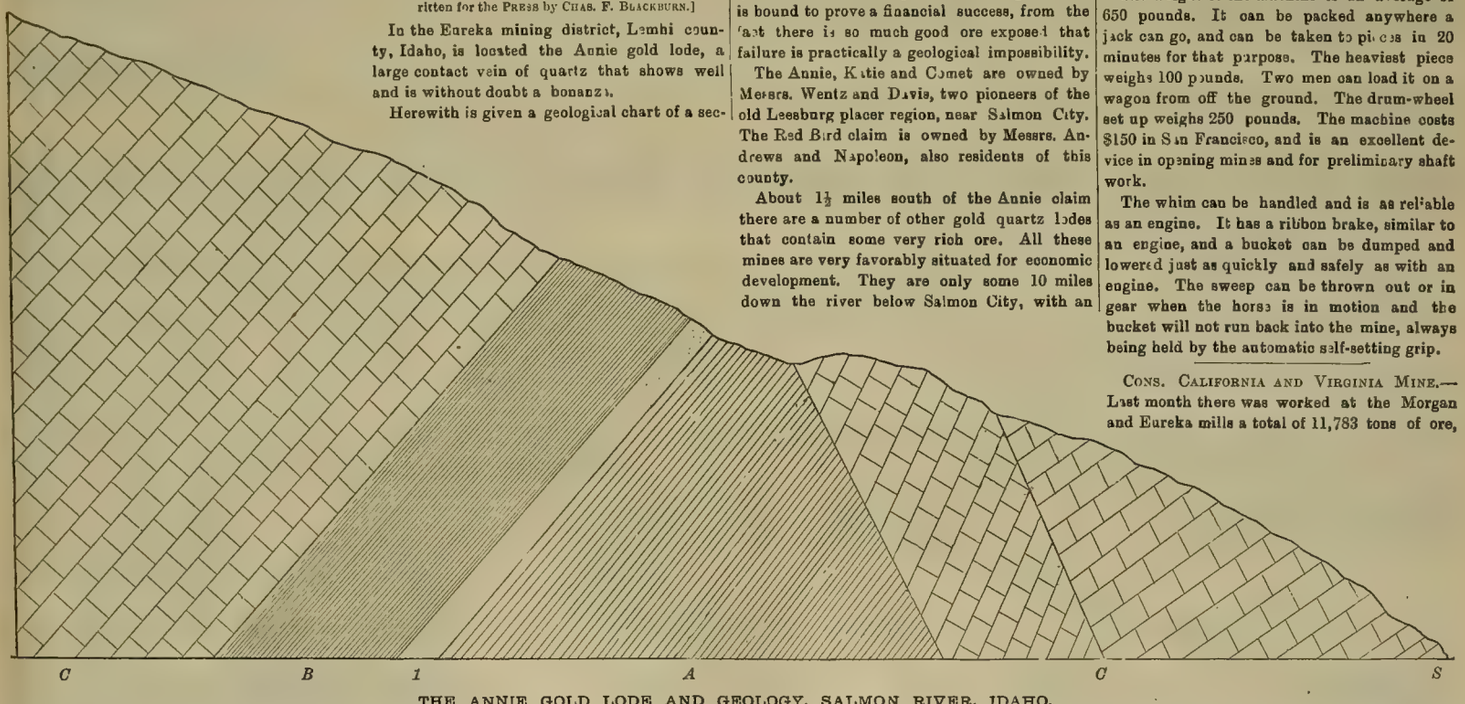
The Annie, Katie and Comet are owned by Messrs. Wentz and Davis, two pioneers of the old Leesburg placer region, near Salmon City. The Red Bird claim is owned by Messrs. Andrews and Napoleon, also residents of this county.

About 1½ miles south of the Annie claim there are a number of other gold quartz lodes that contain some very rich ore. All these mines are very favorably situated for economic development. They are only some 10 miles down the river below Salmon City, with an abundance of wood and water on the ground.

Were mining capitalists seeking good free-milling gold quartz properties to visit this region they could certainly find what they want and secure some rare bargains. The veins are numerous, rich, and show an abundance of ore, considering the amount of work done.

The snow is now off except on the high ranges. The grass and wild flowers are up. Salmon trout are coming up the river by the thousand. A man can catch more trout here in one hour than he can pack. These fine, large trout are a bonanza for the bear and Indians.

The placer miners and quartz prospectors are beginning their annual "rustle," and this promises to be a busy and profitable year for both parties in this region. The Salmon river country is a great field, rich and rough, and even 50 or 100 years hence there will be good mines found in this at present almost terra incognita. The mining future of this region is indeed bright. The day is approaching when the stream of gold and silver pouring from these mountains will amount to tens of millions yearly. This conclusion is based upon irrefutable geological evidence.



THE ANNIE GOLD LODE AND GEOLOGY, SALMON RIVER, IDAHO.

A New Steel Whim.

The "Common-sense" whim made by the Risdon Iron Works of this city is all made of metal. The arms of the wheel are bolted to the hub and to the rim of the drum and can be taken to pieces for transportation on pack-animals. The one-horse whim has a drum six feet in diameter and will wind 500 feet of rope. The sweep is thrown up out of gear by forcing a wedge shaped piece of iron under the shaft; this gives great power, and when the horse gets the bucket up to the sheave and *won't stop*, it can be thrown out of gear, allowing the horse to go on around the circle, the automatic grip holding the load.

In the new steel whim illustrated on this page, the makers have done away with about one-half of the castings used in the former whim and substituted wrought iron and steel for them. This brings the chances for accidents down to a minimum. The one-horse whim will raise the weight of an oil-barrel filled with horseshoes.

This whim runs lightly, less than one-pound pressure on the end of the sweep turning the empty drum-wheel when no rope or brake is attached. When the kingpost is bolted down, put the drum-wheel on, give it a whirl and it will run around five or six times without stopping.

The speed at which it can hoist is, with an ordinary-gaited horse, about 80 feet per minute. A day's work of ten hours is about 100 buckets from a depth of 300 feet. A horse has three to one leverage; a 200-pound pull on the single tree will raise a 60-pound bucket.

The weight of the machine is an average of 650 pounds. It can be packed anywhere a jack can go, and can be taken to pieces in 20 minutes for that purpose. The heaviest piece weighs 100 pounds. Two men can load it on a wagon from off the ground. The drum-wheel set up weighs 250 pounds. The machine costs $150 in San Francisco, and is an excellent device in opening mines and for preliminary shaft work.

The whim can be handled and is as reliable as an engine. It has a ribbon brake, similar to an engine, and a bucket can be dumped and lowered just as quickly and safely as with an engine. The sweep can be thrown out or in gear when the horse is in motion and the bucket will not run back into the mine, always being held by the automatic self-setting grip.

CONS. CALIFORNIA AND VIRGINIA MINE.—Last month there was worked at the Morgan and Eureka mills a total of 11,783 tons of ore, yielding bullion of the gross value of $338,456 02, of which $152 300.95 was in gold and $186,155 07 was silver. The average yield of the ore in bullion per ton was $28 72, and the average assay value of the battery samples was $33.89 per ton.

THE report of the Standard Consolidated mine for the fiscal year ending February 1st shows $127,341 in bullion and $40,000 paid in dividends. The disbursements for the year were $231,686, and the amount charged to profit and loss $88,962. A cash balance of $20,064 was carried forward to the account of the new year.

REDUCTION WORKS CONSOLIDATION.—At a meeting of the directors of the reduction works, held at Deadwood, Dakota, it was decided to consolidate with the Golden Regard Company, the stock of both companies being changeable into the stock of the new company.

SAWMILL NOTES.

A Double-Acting Band-Saw Mill.

A couple of Michigan men have taken out patents upon a band-mill carrying two saws, which is designed to cut in both directions, so that no time is lost in the process of gigging back. A board is cut from the log in running one way by one of the saws, and another by the other saw in returning. It was a Chicago lumber trade journalist who suggested some months ago that the ultimate function of the band-mill would be to do some such thing as this.

Naturally the increase in the number of saws and in the necessary amount of gearing is calculated to require increased power to propel it, but if the capacity of the saw is doubled this should not be a serious drawback. In a machine shop in this city there still stands a band-mill carrying two saws, in the success of which the intrepid inventor had much confidence, but this confidence has not yet been shared by any millman by the practical application of the invention.

Sawmill men are chary of new things in the band-mill line. In some quarters the mills which have been proven successful are looked upon with suspicion even yet, and innovations have as much difficulty in getting an opportunity as the stage struck maiden to get an engagement as leading lady in a first-class theatrical company.

Still it is entirely probable that the capacity of the band-mill will be increased, and that the attention the principle is receiving at the hands of inventive minds will result in many changes and improvements.

The idea contained in the latest invention is not a bad one, and a double band-mill, saving time chiefly which would otherwise be consumed in gigging, would not be open to the objection which a mill cutting two boards at one time might be, for obvious reasons.—*Mississippi Valley Lumberman.*

Lively Demand for Sawmill Machinery.

There is a lively demand for sawmill machinery all through the Western and Southern States. In addition to new mills and machinery there is also a great demand for reconstruction and for improved machinery. Time was—and that not long ago—when the builder of sawmill machinery contented himself with looking after new mill enterprises and incidental repairs here and there. Of course there were additions of new machinery now and then, but no such revolutionary reconstruction as is now going on in a great many mills. The sharp competition in the lumber trade has proven a friend to the machinery-maker. The best inventive genius is taxed to keep up with the demand for first class machinery, and the millmen are showing a commendable disposition everywhere to keep up with the times.

This branch of manufacture has gradually developed from small beginnings, until the best saws in the world are now made in the United States. In this direction American industry has achieved a signal triumph, and while the foreign producer is beaten at every point, a growing important export business has sprung up in American saws of late. A St. Paul journal says that there is something of a hitch in the business, just at this time, in the South. It claims that a good many of the manufacturers of sawmill machinery who have enjoyed a generous trade in the South, are not finding their experience an altogether happy one. They find plenty of trade, but there is internal evidence that the Southern lumbermen, as a class, have not made money. It is easier to sell the machinery, then, than to collect pay for it.

A LARGE SAWMILL.—A sawmill has lately been erected at Brewton, Ala., which is a monster in size. Over 3,000,000 feet of lumber were used in the erection of the mill and the buildings connected with it. The logging ditch is 14 miles long. One mile of rails are used in the drying-kilns and transfer-tracks. The gang of 36 saws, with rotary, edger, cut-off, lath and shingle machines, etc., will be driven by two engines, 24x36 and 20x30, which are fed by four 60-inch by 16-foot tubular boilers. More than 6000 cubic yards of earth have been removed from the creek to prepare a suitable and satisfactory log pond, from which will be drawn 1000 logs a day when the mill is in operation. In the planing-mill, which is 164x288 feet, ten cars can be loaded at one time, regardless of wind or weather. In front of the planers 24 trucks of lumber can stand ready to be pushed through the four flooring-mills, or surfacers—and at the end of these flooring-mills the board lands on an endless chain, which carries it to any of the cars, or to the pile where it is intended to place it. A million and a half feet of dressed lumber can be stored without infringing upon the loading space.

SAWMILL FOR SMALL POWER.—The Salem Iron Works of Salem, N. C., are putting on the market an improved sawmill for small power, having been specially designed for farmers—for example, who have a small water or steam power, but do not care to invest in an expensive mill. It is not intended for doing a large lumbering business, or for sawing long and large logs, but for those who want a good, cheap mill for their own use and do not care to saw logs over three feet in diameter or 16 feet in length. Each mill is provided with an improved double eccentric friction feed, adjustable mandrel-boxes, wedge-wheel, long rest, saw guide, and enough improved conical rollers and boxes to go on ways twice the length of carriage.
